#### Abstract

Based on the conjugacy condition often which is satisfy by quasi-Newton method, the new version of DY nonlinear conjugate gradient method is proposed, which is descent methods even with inexact line searches. The search direction of the proposed method has the form $d_{k+1}=-\theta_{k+1} g_{k+1} \beta_{k} d_{k}$. When exact line search is used, the proposed method reduce to the standard DY method. Convergence properties of the proposed method is discussed. Numerical results are reported.

Key Words: Conjugate gradient algorithm, DY-Algorithm, descent direction, global convergence.

في هذا البحث قمنا بدراسة خواص النقارب الثمولي ، ووضعت المبرهنات الخاصة بها التي تعزز هذه الخواص.

## 1-Introduction:

We concerned with the unconstrained minimization problem
Minimize $\mathrm{f}(\mathrm{x}), x \in R^{n}$
where $\quad f: R^{n} \rightarrow R$ is smooth and its gradient $g(x)=\nabla f(x)$ is available. There are several kinds of numerical methods for solving [1], which include for example, the steepest descent, the Newton method and quasi-Newton method.

Among them, the conjugate gradient method is one choice for solving large scale problems, because it does not need any matrices $[1,2,3]$
Conjugate gradient methods are iterative methods of the form given by:

$$
\begin{equation*}
x_{k+1}=x_{k}+\alpha_{k} d_{k}, \tag{2}
\end{equation*}
$$

where $\alpha_{k}>0$ is a positive step size and $d_{k}$ is a search direction. The search direction are usually defined by:

$$
d_{k+1}= \begin{cases}-g_{k+1} & \text { if } k=0  \tag{3}\\ -g_{k+1}+\beta_{k} d_{k}, & \text { if } k \geq 1\end{cases}
$$

where $\quad g_{k+1}=\nabla f\left(x_{k+1}\right) \quad$ and $\quad \beta_{k} \in R$ is scalar parameter which characterizes conjugate gradient methods [4].
Usually the parameter $\beta_{k}$ is chosen so that $[2,3]$ reduces to linear conjugate gradient method if $\mathrm{f}(\mathrm{x})$ is strictly convex quadratic function and if $\alpha_{k}$ is calculated by the exact line search. Several kind of formulas for $\beta_{k}$ has been proposed, for example, the Hestens-Stiefel (HS), Fletcher-Reeves (FR), Polak-Ribie're (PR), Liu-Storey (LS) and DaiYaun (DY) formula [5], [6], [7], [8], [9]\& [10].

$$
\begin{align*}
& \beta_{k}^{H S}=\frac{g_{k+1}^{T} y_{k}}{d_{k}^{T} y_{k}}  \tag{4}\\
& \beta_{k}^{F R}=\frac{\left\|g_{k+1}\right\|^{2}}{\left\|g_{k}\right\|^{2}}  \tag{5}\\
& \beta_{k}^{P R}=\frac{g_{k+1}^{T} y_{k}}{\left\|g_{k}\right\|^{2}}  \tag{6}\\
& \beta_{k}^{L S}=-\frac{g_{k+1}^{T} y_{k}}{d_{k}^{T} g_{k}}  \tag{7}\\
& \beta_{k}^{D Y}=\frac{\left\|g_{k+1}\right\|^{2}}{d_{k}^{T} y_{k}} \tag{8}
\end{align*}
$$

where $y_{k}=g_{k+1}-g_{k}$ and $\|$.$\| denote the Euclidean$ norm. If $f(x)$ is strictly convex quadratic function

$$
\begin{equation*}
f(x)=\frac{1}{2} x^{T} G x+b^{T} x \tag{9}
\end{equation*}
$$

where $G \in R^{n x n}$ is a symmetric positive definite matrix, and if $\alpha_{k}$ is the exact one-dimensional minimizer then the method (2) and (3) is called the linear conjugate method, within the framework of linear conjugate gradient methods, the conjugacy condition is defined by

$$
\begin{equation*}
d_{i}^{T} G d_{j}=0, i \neq j \tag{10}
\end{equation*}
$$

for search direction, and this condition guarantees the finite termination of the linear conjugate gradient methods. On the other hand, the method (2) and (3) is called the nonlinear conjugate gradient method for several unconstrained optimization problem. The conjugacy condition is replaced by

$$
\begin{equation*}
d_{k+1}^{T} y_{k}=0 \tag{11}
\end{equation*}
$$

for search direction, because the relations:

$$
\begin{align*}
d_{k+1}^{T} G d_{k} & =\frac{1}{\alpha_{k}} d_{k+1}^{T} G\left(x_{k+1}-x_{k}\right) \\
& =\frac{1}{\alpha_{k}} d_{k+1}^{T}\left(g_{k+1}-g_{k}\right) \\
& =\frac{1}{\alpha_{k}} d_{k+1}^{T} y_{k} \tag{12}
\end{align*}
$$

holds for strictly convex quadratic objective function. The extension of the conjugacy condition was studied by Perry [11] and also Shanno [15].
However, both the conjugacy condition (10) and (11) depend on exact line search. In particular computation, one normally carries on inexact line search instead of exact line search. In the case when $g_{k+1}^{T} d_{k} \neq 0$, the conjugacy condition (10) and (11) may have some disadvantages, for this season the extension of the conjugacy condition studied by Perry [11]. He tried to accelerate the conjugate gradient method by incorporating the second-order information into it, specifically, he used the quasi-Newton method, when the search direction $d_{k}$ can be calculated in the form:

$$
\begin{equation*}
d_{k+1}=-H_{k+1} g_{k+1} \tag{13}
\end{equation*}
$$

where $H_{k+1}$ is nxn symmetric and positive definite and with quasi-Newton condition defined by:

$$
\begin{equation*}
H_{k+1} y_{k}=s_{k} \tag{14}
\end{equation*}
$$

where $s_{k}=x_{k+1}-x_{k}=\alpha_{k} d_{k}$. For quasi-Newton method, by (13) and (14), we have that

$$
\begin{gather*}
d_{k+1}^{T} y_{k}=-\left(H_{k+1} g_{k+1}\right)^{T} y_{k} \\
=-g_{k+1}^{T}\left(H_{k+1} y_{k}\right) \\
=-g_{k+1}^{T} s_{k} \tag{15}
\end{gather*}
$$

equation (15) is called Perry's condition, which implies (11) hold if the line search is exact, since in this case $g_{k+1}^{T} s_{k}=0$.

However, practical algorithms normally adopt inexact line searches instead of exact line searches. Recently Dai and Liao [13] replace the conjugacy condition (11) with the condition:

$$
\begin{equation*}
d_{k+1}^{T} y_{k}=-t g_{k+1}^{T} s_{k} \tag{16}
\end{equation*}
$$

where $t \geq 0$ is a scalar. In the case $\mathrm{t}=0$, (16) reduces to the usual conjugacy condition (11). On the other hand, in then case $t=1$, (16) becomes Perry's condition (15).

To establish convergence properties of any method, it is usually required that the step size $\alpha_{k}$ should satisfy the strong Wolfe conditions:
$f\left(x_{k}+\alpha_{k} d_{k}\right)-f\left(x_{k}\right) \leq \delta \alpha_{k} g_{k}^{T} d_{k}$ (17)
$\left|g\left(x_{k}+\alpha_{k} d_{k}\right)^{T} d_{k}\right| \leq-\sigma g_{k}^{T} d_{k}$
where $o<\delta<\sigma<1$ [14]. On other hand, many other numerical methods (e.g. the steepest descent and quasi-Newton methods) for unconstrained optimization are proved to be convergent under the Wolfe conditions, which are weaker than the strong Wolfe conditions:

$$
\begin{align*}
& f\left(x_{k}+\alpha_{k} d_{k}\right)-f\left(x_{k}\right) \leq \delta \alpha_{k} g_{k}^{T} d_{k}  \tag{19}\\
& g^{T}\left(x_{k}+\alpha_{k} d_{k}\right)^{T} d_{k} \geq \sigma g_{k}^{T} d_{k} \tag{20}
\end{align*}
$$

thus it is an interesting to study global convergence of conjugate gradient methods under the Wolfe conditions instead of the strong Wolfe condition [15] \& [16].
Besides conjugate gradient methods, the following gradient type methods
$d_{k+1}= \begin{cases}-g_{k+1} & , \text { if } k=0 \\ -\theta_{k+1} g_{k+1}+\beta_{k} d_{k}, & \text { if } k \geq 1\end{cases}$
have also been studied extensively by many authors, here $\theta_{k+1}$ and $\beta_{k}$ are two parameters. Clearly, if $\theta_{k+1}=1$, the methods (21) becomes conjugate gradient method (3). Zhang et al [17] proposed a modified FR-method where the parameter in(21) are given by:
$\theta_{k+1}=\frac{d_{k}^{T} y_{k}}{\left\|g_{k}\right\|^{2}}$ and $\beta_{k}=\beta_{k}^{F R}=\frac{\left\|g_{k+1}\right\|^{2}}{\left\|g_{k}\right\|^{2}}$
This method satisfied $g_{k+1}^{T} d_{k+1}=-\left\|g_{k+1}\right\|^{2}$. Moreover, this method convergences globally for general function with Armijo or Wolfe line search. Brigin and Martinez [4] proposed a special conjugate gradient method by combining conjugate gradient method and spectral gradient method [18] in the following way
$d_{k+1}=-\theta_{k+1} g_{k+1}+\beta_{k} d_{k}$,
where $\quad \theta_{k+1}$ and $\beta_{k}$ is parameter and $\beta_{k}=\frac{\left(\theta_{k+1} y_{k}-s_{k}\right)}{d_{k}^{T} y_{k}}$ and $\theta_{k+1}=\frac{s_{k}^{T} s_{k}}{s_{k}^{T} y_{k}}$,
Andrei [2] proposed another conjugate gradient method where the search direction is selected as

$$
d_{k+1}=-\theta_{k+1} g_{k+1}+\beta_{k}^{D L} d_{k},
$$

where

$$
\beta_{k}^{D L}=\left(\frac{y_{k}^{T} g_{k+1}}{y_{k}^{T} s_{k}}\right) s_{k}-t\left(\frac{s_{k}^{T} g_{k+1}}{y_{k}^{T} s_{k}}\right) s_{k} \text {. }
$$

In this paper, we are concerned with the methods (21) with the parameter $\beta_{k+1}=\beta_{k+1}^{D Y}$, because Dai and Yaun method always generates descant direction and under Lipschitz assumption its globally convergent. Then we try to construct new $\theta_{k+1}$ by using the idea of DY method [10].
This paper is organized as follows. In Section 2, we present new formulas for $\theta_{k+1}$ corresponding algorithms, and prove a descent search direction. In section 3, we analyze global properties of the proposed method with inexact line searches, In Section 4, we report numerical comparison with existing conjugate gradient methods.

## 2-New Formula for $\theta_{k+1}$ and Algorithms

In this section we present a modified of the Dai and Yuan computational method, we describe the following two-terms DY conjugate gradient type method

$$
d_{k+1}=\left\{\begin{array}{lr}
-g_{k+1} & \text { if } k=0  \tag{22}\\
-\left(1+\theta_{k+1}^{l}\right) g_{k+1}+\beta_{k}^{D Y} & d_{k}, \text {, } k=1
\end{array}\right.
$$

where, for convenience, we write $\theta_{k+1}=1+\theta_{k+1}^{l}$, and $\theta_{k+1}^{l}$ is positive parameter.
In order to get the formula for $\theta_{k+1}^{l}$ in our method, multiply both sides of (22) by $y_{k}$.
$d_{k+1}^{T} y_{k}=-g_{k+1}^{T} y_{k}-\theta_{k+1}^{l} g_{k+1}^{T} y_{k}+\beta_{k}^{D Y} d_{k}^{T} y_{k}$ (23) sub stituting (16) and (8) into (23), we have
$-\operatorname{tg}_{k+1}^{T} s_{k}=-g_{k+1}^{T} y_{k}-\theta_{k+1}^{l} g_{k+1}^{T} y_{k}+\left\|g_{k+1}\right\|^{2}$ so, we have

$$
\begin{aligned}
& \theta_{k+1}^{l} g_{k+1}^{T} y_{k}=t g_{k+1}^{T} s_{k}+\left\|g_{k+1}\right\|^{2}-g_{k+1}^{T} y_{k} \\
& \theta_{k+1}^{l}=t \frac{g_{k+1}^{T} s_{k}}{g_{k+1}^{T} y_{k}}+\frac{\left\|g_{k+1}\right\|^{2}}{g_{k+1}^{T} y_{k}}-1, \\
& \theta_{k+1}^{l}=t \frac{g_{k+1}^{T} s_{k}}{g_{k+1}^{T} y_{k}}+\frac{\left\|g_{k+1}\right\|^{2}}{g_{k+1}^{T} y_{k}}\left(\frac{g_{k+1}^{T} s_{k}}{g_{k+1}^{T} s_{k}}\right)-1
\end{aligned}
$$

then

$$
\begin{equation*}
\theta_{k+1}^{l}=t \frac{g_{k+1}^{T} s_{k}}{g_{k+1}^{T} y_{k}}+\frac{\left\|g_{k+1}\right\|^{2}}{s_{k}^{T} y_{k}}\left(\frac{g_{k+1}^{T} s_{k}}{\left\|g_{k+1}\right\|^{2}}\right)-1 \tag{24}
\end{equation*}
$$

since, t is parameter, let t be defined by:

$$
\begin{equation*}
t=\frac{g_{k+1}^{T} y_{k}}{g_{k+1}^{T} s_{k}}-\rho \frac{g_{k+1}^{T} y_{k}}{s_{k}^{T} y_{k}} \tag{25}
\end{equation*}
$$

where $\rho$ is constant and $\rho \in[0,1)$. Then, we have

$$
\theta_{k+1}^{l}=\frac{\left\|g_{k+1}\right\|^{2}}{s_{k}^{T} y_{k}}\left(\frac{g_{k+1}^{T} s_{k}}{\left\|g_{k+1}\right\|^{2}}\right)-\rho \frac{g_{k+1}^{T} s_{k}}{s_{k}^{T} y_{k}}
$$

since $s_{k}=\alpha_{k} d_{k}$

$$
\begin{equation*}
\theta_{k+1}^{l}=\beta_{k}^{D Y} \frac{g_{k+1}^{T} d_{k}}{\left\|g_{k+1}\right\|^{2}}-\rho \frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}} \tag{26}
\end{equation*}
$$

then the new scalar $\theta_{k+1}$ is defined by

$$
\begin{align*}
\theta_{k+1} & =1+\theta_{k+1}^{l} \\
= & 1+\beta_{k}^{D Y} \frac{g_{k+1}^{T} d_{k}}{\left\|g_{k+1}\right\|^{2}}-\rho \frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}} \tag{27}
\end{align*}
$$

For convenience, we summarize the above method as the following algorithm which we call the twoterm DY method.

### 2.1 Algorithm of two-term DY method (modified DY method)

Step(0): Given $x_{1} \in R^{n} \quad, \varepsilon>0$, set $d_{1}=-g_{1}=-\nabla f\left(x_{1}\right)$, if $\left\|g_{1}\right\|<\varepsilon$ then stop.

Step (1): Find $\alpha_{k}>0$ satisfying the Wolfe condition (19) and (20)
$\operatorname{Step}(\mathbf{2})$ : Let $x_{k+1}=x_{k}+\alpha_{k} d_{k}$ and $g_{k+1}=g\left(x_{k+1}\right)$.
If $\left\|g_{k+1}\right\|<\varepsilon$, then stop; Otherwise continue. Step(3): Compute $\beta_{k}, \theta_{k+1}$ by the formula (8), (27), respectively and generate the new search direction $d_{k+1}$ by (22).
$\operatorname{Step}(4):$ If $\mathrm{k}=\mathrm{n}$ or $\left\|g_{k+1}^{T} g_{k}\right\|>0.2\left\|g_{k+1}\right\|^{2}$ is satisfy, go to step (0), else $\mathrm{k}=\mathrm{k}+1$ and go to step (1).

Note, if exact line search is used, it is easily to see that the algorithm (2.1) reduce to the standard DY method.

### 2.2 The Sufficient Descent Condition.

In the global convergence analysis for many methods, the sufficient descant condition, namely for some constant $\mathrm{c}>0$ ( c is positive constant).

$$
\begin{equation*}
g_{k+1}^{T} d_{k+1} \leq-c\left\|g_{k+1}\right\|^{2} \tag{28}
\end{equation*}
$$

This condition has been used to analyze the global convergence of conjugate gradient Algorithms with inexact line searches [1]. The following result shows that algorithm (2.1) produces sufficient descent directions.

Lemma 2.2.1
Let $\left\{x_{k}\right\}$ and $\left\{d_{k}\right\}$ be generated by Algorithm (2.1), and let $\alpha_{k}$ be obtained by the Wolfe line search (19) and (20), if $\rho \in[0,1)$, then we have

$$
\begin{equation*}
\frac{g_{k+1}^{T} d_{k+1}}{\left\|g_{k+1}\right\|^{2}} \leq-c \tag{29}
\end{equation*}
$$

where $c=[1+\rho \sigma /(1-\sigma)]$.
Proof:
Note, that when $\rho=0$ in (27) then (22), become:

$$
\begin{aligned}
d_{k+1}^{T} g_{k+1} & =-\left\|g_{k+1}\right\|^{2}-\beta_{k}^{D Y} g_{k+1}^{T} d_{k}+\beta_{k}^{D Y} g_{k+1}^{T} d_{k} \quad \text { For } \\
& =-\left\|g_{k+1}\right\|^{2} .
\end{aligned}
$$

initial direction ( $\mathrm{k}=1$ ) we have :

$$
d_{1}=-g_{1} \Rightarrow d_{1}^{T} g_{1}=-\left\|g_{1}\right\|^{2}<0
$$

Suppose

$$
g_{j}^{T} d_{j}<0, \quad \forall j=1,2, \ldots, k
$$

We have from (22) and the definition of $\beta^{D Y}$ (8) that:

$$
g_{k+1}^{T} d_{k+1}=-\left\|g_{k+1}\right\|^{2}+\rho \frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}}\left\|g_{k+1}\right\|^{2}(30)
$$

Which implies that:

$$
\begin{aligned}
\frac{g_{k+1}^{T} d_{k}}{\left\|g_{k+1}\right\|^{2}} & =-1+\rho \frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}} \\
& =-1+\rho-\rho+\rho \frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}}
\end{aligned}
$$

$$
\begin{array}{r}
=-(1-\rho)-\rho\left(1-\frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}}\right) \\
\text { since, }\left(1-\frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}}\right)=-\frac{g_{k}^{T} d_{k}}{d_{k}^{T} y_{k}} \\
\frac{g_{k+1}^{T} d_{k}}{\left\|g_{k+1}\right\|^{2}}=-(1-\rho)+\rho \frac{g_{k}^{T} d_{k}}{d_{k}^{T} y_{k}}
\end{array}
$$

from the Wolfe condition (20)

$$
\begin{aligned}
y_{k}^{T} d_{k} & \geq-(1-\sigma) g_{k}^{T} d_{k} \\
\frac{g_{k+1}^{T} d_{k+1}}{\left\|g_{k+1}\right\|^{2}} & \leq-(1-\rho)-\rho \frac{g_{k}^{T} d_{k}}{(1-\sigma) g_{k}^{T} d_{k}} \\
& =-[1+\rho \sigma /(1-\sigma)] .
\end{aligned}
$$

Since $0<\sigma<1$ then let $c=[1+\rho \sigma /(1-\sigma)]$ is positive constant i.e.

$$
g_{k+1}^{T} d_{k+1} \leq-c\left\|g_{k+1}\right\|^{2}
$$

The proof is complete.

## 3- Convergence Analysis

For the global converge analysis of many methods, the following assumption is often needed.

Assumption (1):
i-The level $\Psi=\left\{x \in R^{n} / f(x) \leq f\left(x_{0}\right)\right\} \quad$ is bounded.
ii- In some neighborhood $\Omega$ of $\psi$, f is continuously differentiable and its gradient is Lipschitz continuous, i.e. there exists a constant L>o, such that
$\|g(x)-g(y)\| \leq L\|x-y\|, \forall x, y \in \Omega(31)$
Clearly Assumption (1) implies that, their exists a constant $\gamma \geq 0$, such that

$$
\begin{equation*}
\|g(x)\| \leq \gamma, \forall x \in \Omega \tag{32}
\end{equation*}
$$

The following Lemma, called the Zountendijk condition is often used to prove global convergence of conjugate gradient methods holds and consider It was originally given by [19],[20].

## Lemma 3.1

Suppose that Assumption (1) holds. Consider any iteration method of the form (1) and (2), where $d_{k}$ satisfies descent direction $g_{k}^{T} d_{k}<0$ and $\alpha_{k}$ is obtained by the Wolfe conditions or the strong Wolfe conditions, then the following holds

$$
\begin{equation*}
\sum_{k=0}^{\infty} \frac{\left(g_{k}^{T} d_{k}\right)^{2}}{\left\|d_{k}\right\|^{2}}<+\infty \tag{33}
\end{equation*}
$$

or equivalently

$$
\begin{equation*}
\sum_{k=0}^{\infty}\left\|g_{k}\right\|^{2} \cos ^{2} \phi_{k}<\infty \tag{34}
\end{equation*}
$$

where $\phi_{k}$ is the angel between the search direction $d_{k}$ and the steepest descent direction $-g_{k}$ [21].

## Theorem 3.2

Suppose that Assumption (1) holds, if $\rho \in[0,1)$, where the sequence $\left\{x_{k}\right\}$ generated by Algorithm (2.1) with the Wolfe line search then (19)\& (20) satisfies

$$
\begin{equation*}
\liminf _{k \rightarrow \infty}\left\|g_{k}\right\|=0 \tag{35}
\end{equation*}
$$

## Proof:

We will using the contradiction for prove theorem (3.2), i.e. if the theorem is not true, then $\left\|g_{k}\right\| \neq 0$, then there exists $\gamma>0$, such that

$$
\|g(x)\|>\gamma, \quad \forall k
$$

Then, from (30)

$$
\begin{align*}
& d_{k+1}^{T} g_{k+1}=-\left\|g_{k+1}\right\|^{2}+\rho \frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}}\left\|g_{k+1}\right\|^{2} \\
& \frac{g_{k+1}^{T} d_{k+1}}{\left\|g_{k+1}\right\|^{2}}+1=\rho \frac{g_{k+1}^{T} d_{k}}{d_{k}^{T} y_{k}} \tag{36}
\end{align*}
$$

Use second Wolfe condition (20) and Lipschitz condition (32) for $d_{k}^{T} y_{k} \leq L d_{k}^{T} s_{k}$. Therefore

$$
\begin{aligned}
\frac{g_{k+1}^{T} d_{k+1}}{\left\|g_{k+1}\right\|^{2}} & +1 \geq \rho \frac{g_{k}^{T} d_{k}}{L d_{k}^{T} s_{k}} \\
& \geq \rho \frac{\sigma g_{k}^{T} d_{k}}{L \alpha_{k}\left\|d_{k}\right\|^{2}}
\end{aligned}
$$

Then

$$
\begin{equation*}
\frac{L \alpha_{k}}{\rho \sigma}\left(\frac{d_{k+1}^{T} g_{k+1}}{\left\|g_{k+1}\right\|^{2}}+1\right) \geq \frac{g_{k}^{T} d_{k}}{\left\|d_{k}\right\|^{2}} \tag{37}
\end{equation*}
$$

Take the squares of both sides to (37), we get

$$
\begin{aligned}
& \qquad\left(\frac{L \alpha_{k}}{\rho \sigma}\right)^{2}\left(\frac{d_{k+1}^{T} g_{k+1}}{\left\|g_{k+1}\right\|^{2}}+1\right)^{2} \geq\left(\frac{g_{k}^{T} d_{k}}{\left\|d_{k}\right\|^{2}}\right)^{2} \\
& \text { Since } \quad\left(g_{k}^{T} d_{k}\right)^{2}=\left\|g_{k}\right\|^{2}\left\|d_{k}\right\|^{2} \cos ^{2} \phi_{k}
\end{aligned}
$$

Then
$\eta\left(\frac{d_{k+1}^{T} g_{k+1}}{\left\|g_{k+1}\right\|^{2}}+1\right)^{2} \geq\left\|g_{k}\right\|^{2} \cos ^{2} \phi_{k} \geq \gamma^{2} \cos ^{2} \phi_{k} \mathrm{w}$
here, $\eta=\left(\frac{L \alpha_{k}}{\rho \sigma}\right)^{2}\left\|d_{k-1}\right\|^{2}$.
Taking the summation from $\mathrm{k}=1$ to $\mathrm{k}=\infty$, we get

$$
\begin{aligned}
\sum_{k \geq 1}^{\infty} \eta\left(\frac{g_{k+1}^{T} d_{k+1}}{\left\|g_{k+1}\right\|^{2}}+1\right)^{2} & \geq \sum_{k \geq 1}^{\infty} \frac{\left(g_{k}^{T} d_{k}\right)^{2}}{\left\|d_{k}\right\|^{2}} \\
& \geq \sum_{k \geq 1}^{\infty} \gamma^{2} \cos ^{2} \phi_{k}=\infty
\end{aligned}
$$

Contradiction with Zountendijk theorem. Therefore $\liminf _{k \rightarrow \infty}\left\|g_{k}\right\|=0$.

## 4- Numerical results

We testes the HS, FR, PR and DY formulas (4), (5), (6) and (8) respectively and our new method (modified of the DY method) (22), (27). All results are obtained using Pentium 4 workstation and all programs are written in Fortran Language. Our line search subroutine compute $\alpha_{k}$ such that the Wolfe condition (19) $\&(20)$ holds with $\delta=0.001$, and $\rho=0.9$ the value of $\alpha_{k}$ is always compute by cubic fitting procedure which was described in details by Bundy [22].
We have tested 14 nonlinear test functions with different dimensions $n=1000,10000$ and also higher dimension like $\mathrm{n}=100000$, 1000000. The numerical results are given in the form of NOI and NOF ( number of iterations and number of function evaluations). The stopping condition used was $\left|g_{k+1}\right| \leq 1 \times 10^{-5}$.
Comparing the new method with HS, FR, PR and DY formulas we could say that the new method is more better than all especially for large dimensions.
In order to get relatively better $\rho$ values in Algorithm (2.1), we choose 14 complex problems to test Algorithm (2.1) with different $\rho$ values. (Table 1) lists these numerical results where NOF and NOI mean the number of function evaluations and the number of iterations.
In (Table 1), we see that Algorithm (2.1) with $\rho=0.5$ performed best. Moreover, we also compared Algorithm (2.1) with other Algorithms
in the previous sections and numerical results showed that they performed similarly. So in this section, we only listed the numerical results for Algorithms (2.1) with $\rho=0.5$. These results are reported in (Table 2). The symbol * in (Table 1) and (table 2) means that the algorithm is unable to solve the particular problem.

Table 1: Test results for Algorithm(2.1) with different $\rho$ values.

| Test functions (n) | $\rho$ | NOI | NOF | Test functions (n) | $\rho$ | NOI | NOF |
