

Determination of vasicine alkaloid efficacy as inhibitor to the activity of protease produced by a clinical isolate of *Pseudomonas aeruginosa*

Ruaa H. Ali*, Majid R. Majeed, Hiba A. Jasim

Department of Biotechnology, College of Science, University of Baghdad, Baghdad, Iraq

Abstract

In the present study, the effect of vasicine alkaloid separated from *Adhatoda vasica* as an inhibitor agent on the activity of proteases enzyme isolated from *Pseudomonas aeruginosa* was investigated. forty isolates of *Pseudomonas aeruginosa* were collected from local hospital in Baghdad and then their ability for producing proteases was screened using quantification and semi- quantitative methods. *Pseudomonas aeruginosa* PI was selected as the highest protease producer, which next identified as *P. aeruginosa*. It was found that the optimum culture conditions for protease production in submerged culture was in the tryptic - soya broth medium at 37° C with pH 8 for 48 hours. In addition, the study involved extraction and partial purification of vasicine alkaloid from crude leaves of *Adhatoda vasica* by separation and precipitation that was 0.6% of vasicine The results revealed a significant effect of the extracted vasicine on the activity of protease enzyme as its activity was decreased from 15.5U / ml to 1.2 U/ml when treated with vasicine at a concentration of 0.8ml with an inhibitory effect of 92.2%.

Keywords: vasicine, *A. vasica*, Protease, *P. aeruginosa*, inhibitory activity.

تحديد فعالية قلويد الفازيسين كمثبط لنشاط البروتيز الذي تنتجه عزلة سريرية من الزوائف الزنجارية

قسم التقنيات الاحيائية، كلية العلوم، جامعة بغداد، بغداد، العراق

الخلاصة

في هذه الدراسة ، تم التحقق من تأثير قلويد vasicine المفصول من *Adhatoda vasica* كعامل مثبط لنشاط انزيم البروتيز المعزول من *Pseudomonas aeruginosa*. تم جمع أربعين عزلة من *Pseudomonas aeruginosa* من مستشفيات محلية في بغداد ، ثم تم فحص قدرتها على إنتاج البروتيز باستخدام الطرق الكمية وشبه الكمية. تم اختيار *Pseudomonas aeruginosa* PI كأعلى منتج للبروتيز ، والذي تم تحديده بعد ذلك على أنه *P. aeruginosa*. وقد وجد أن الظروف المثلى لنمو البكتيريا من أجل إنتاج البروتيز في المزروع المغمورة كانت في الوسط الزراعي السائل لتريبتون الصويا عند 37 درجة مئوية عند أس هيدروجيني 8 ولمدة 48 ساعة. بالإضافة إلى ذلك ، اشتملت الدراسة على استخلاص وتنقية قلويدات vasicine من الأوراق الخام لنبات *Adhatoda vasica* بوساطة الفصل والترسيب والذي كان بنسبة 0.6% من vasicine. كشفت النتائج عن تأثير معنوي لقلويد vasicine على نشاط إنزيم البروتيز حيث انخفض نشاطه. من 15.5 U / ml إلى 1.2 U / ml عندما تمت معاملته مع vasicine عند تركيز 0.8 ml مع تأثير مثبط بنسبة 92.2%.

1. Introduction

Microorganisms produced different types of products through metabolism process of different types of substances. Some of these products are poisons that are produced naturally as the final products of the metabolism, these poisons products have accumulated inside the cell called endotoxins or release to the growth media is known as exotoxin, the toxins can be either small peptide molecules or proteins. *Pseudomonas aeruginosa* produce a large number of extracellular toxins which include phytotoxic factor, pigments, hydrocyanic acid, proteolytic enzyme phospholipase, enterotoxin and exotoxin [1]. The most important factor in the pathogenesis of *P. aeruginosa* is developing due to set of exotoxins (protein in nature), External toxins that cause leukopenia, acidosis, breakdown of blood circulation of the liver, pulmonary edema, hemorrhage and tubular necrosis of the kidneys. Passive administration of antitoxic sera against these exotoxins is capable of Protection against deadly infection with *P. aeruginosa* in absence antibodies against cellular antigens [2] reported that *P. aeruginosa* is an opportunistic pathogen and was able to causes intensive morbidity and mortality in individuals who are immune-compromised or have underlying medical conditions such as urinary tract, primarily causes of nosocomial infections, and it is frequently resistant to commonly used antibiotics and disinfectants. Microbial extracellular Protease is a cellular enzyme of *P. aeruginosa* that plays an "important" role in the pathogenesis of bacteria through invasion, concentration, and overcoming the immune defenses of the body [3], that hydrolyze peptide bonds of proteins and break down into polypeptides or free amino acids [4]. proteases which causes bleeding and tissue necrosis. One of the most important characteristics that determine the industrial suitability of proteases is their requirement of high pH for optimum enzyme activity [5]. The occurrence of several tissue damage related diseases associated with free radicals coupled with pathogen resistance to antibiotics has attracted finding alternative remedy against these deleterious molecules and pathogens .A large number of protease inhibitors have been isolated and identified from several plants that medicinal plant are of great importance to the health of individuals and communities in Nigeria and whole world. They contain phytoactive components that possess both curative and preventive properties [6]. for example, *Adhatoda vasica* (L.) belong to the family (Acanthaceae), commonly known as vasaka that Plants have evolved a wide variety of chemical compounds which are known as secondary metabolites were (Coumarines ,Flavones ,Phenolic compound ,Volatiles oil , Tannins , Saponines , Glycosides , Alkaloids , Resins and Terpenoids) [7]. *A. vasica* is widely used in Ayurvedic medicine in India, Sri Lanka and Pakistan due it is bronchodilator,expectorant , antiasthmatic,antiallergic activities against dermatitis and tuberculosis [8]. In china this plant has traditional use against skin disorders. Initial studies showed that the plant possesses anti-inflammatory properties [9]. Therefore, this study aimed to isolation and identification of *P. aeruginosa* from the clinical sample and separation vasicine alkaloid from *Adhatoda vasica* for determination the efficacy of it as inhibitory agent for Protease enzyme that isolated from *P. aeruginosa*.

2. MATERIALS AND METHODS

Collection of bacterial isolates:

Forty clinical samples were collected from burns and infected wounds of patients attending AL-Yarmouk Hospital and Medical City in Baghdad during the period from December 2016 to February 2017.

Identification of *Pseudomonas aeruginosa*:

All collected swabs were cultured on Cetrimide agar, MacConkey agar, and blood agar, and incubated at 37°C for 24hrs under aerobic condition. Bacterial characterization determined depending on cultural characterization, biochemical tests [8], and for more conformation API 20E kit was used.

Determination of protease production from *pseudomonas aeruginosa*.

Semi-quantitative method.

Skim milk-peptone agar was inoculated overnight with bacterial culture and incubated for 24h. at 40°C. Clear zone around the spots and the growth indicate protease production. The diameter of colonies and clear zones were measured. The ratio of clear zone diameter to colony diameter which represents a semi quantitative assay of protease.

Quantitative method.

Ten ml. of casein - peptone broth was inoculated with 0.1 ml of 24h activated bacterial suspension and incubated at 40°C for 24h. The crude enzyme was extracted by centrifugation at 3500 rpm for 20 min . Then the enzyme activity was measured in the supernatant.

Assay of protease activity in samples.

Protease activity was determined according to Sharma et al. (2006) and three replicates for each bacterial isolation. 0.2 mL of the crude enzyme for each bacterial isolation was added to 1.8 ml of reaction solution at 37 °C for 30 min, the blank of protease activity assay consist of 1.8 of reaction solution and 3ml of 5% TCA solution (trichloro acetic acid) without addition of crude enzyme, the reaction was stopped by addition of 3ml of 5% TCA and the mixture was centrifuged for 30 min at 3500rpm and then Supernatant was separated the absorbance (OD) at 280nm was measured enzyme activity was measured according to following equation

$$\text{Activity of enzyme (U/ml)} = \frac{\text{absorbance at 280 nm}}{0.2 \text{ ml} * 0.001 * 30\text{min}}$$

Determination of optimum conditions for protease production.

Production of protease in different media

The bacterial isolate was activated by culturing in nutrient broth and incubated at 37°C for 24h. Each 100ml. of different media was inoculated with 2ml. of bacterial suspension and incubated at 37°C for 24 h. The cells were precipitated by centrifugation at 3500rpm for 20min. The supernatants (crude enzyme) were assayed for enzyme activity for select the best production medium.

Temperature

It was performed with 100 ml of tryptic soya broth medium was inoculated with 2ml. of activated bacterial suspension and incubated at different temperature s (37, 40, and 50°C) for 24h. The supernatant was assayed for enzyme activity

PH value

This was performed with 100 ml. of tryptic soya broth medium was prepared at different pH values (7.0, 8.0, 9.0 and 10.0) adjusted with 1N HCl and 1N NaOH. The medium was inoculated with 2ml. of activated bacterial suspension and incubated at 37°C. for 24h. The supernatant was assayed for enzyme activity.

Incubation period

This was carried out as 100 ml. of tryptic soya broth medium at pH 8 was inoculated with 2ml. of activated bacterial suspension and incubated at 37°C for different times (24, 48 and 72)h. The supernatant was assayed for enzyme activity.

Extraction of Protease

The production medium was inoculated with bacterial suspension and incubated at 37°C. for 48h. The enzyme was extracted by centrifuge at 3500 rpm. for 20min. Activity of enzyme was assay.

Collection and drying of *Adhatoda vasica* leaves

The leaves of *A. vasica* (Acanthaceae) were collected from different places of the gardens of the University of Baghdad. The leaves were washed with clean tap water and then left at room temperature at (22-25) °C for (2-3) weeks for drying; plant leaves were grinded by electric miller to be powder.

Preparation of methanol extracts of plant leaves

Crude leaves extract were prepared by using methanol 80%, dried leaves powder (200gm) and kept in a thimble and extracted by soxhlet apparatus which contained 600ml of the solvent, each separately at 50°C for 36 h with an extraction ratio of (1:3) [10]. Extracted was filtered through a filter paper (whatman No.4) and the filtrate was concentrated by using rotary evaporator. The extract was kept in a glass container at -4°C in a refrigerator.

Estimation of crude extraction ratio for plant leaves

The extraction ratio was determined according to Al Balany (2003) using the following equation.

Concentration extract (yield)

$$\text{ER\%} = \frac{\text{Concentration extract (yield)}}{\text{Initial weight of fresh leaves}} \times 100$$

Initial weight of fresh leaves

Extraction and purification of vasicine

The vasicine alkaloid was isolated from the leaves of *A.vasica* by extracted the leaves with 80% methanol that mentioned in Figure-1 according to [10].

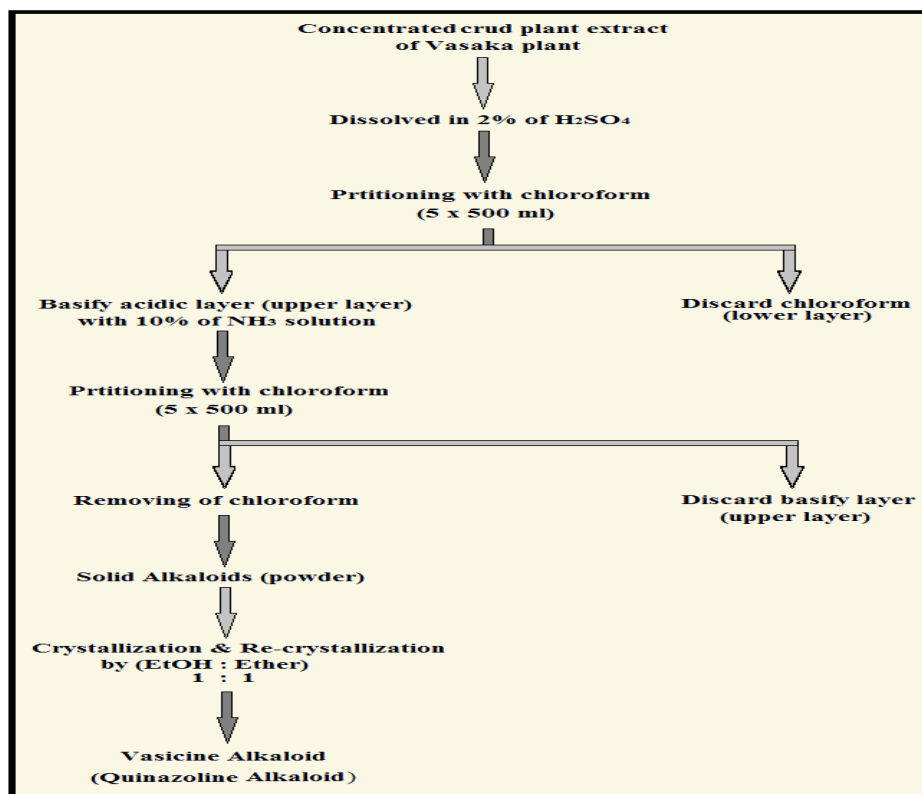

Figure1-Steps of purification procedure of vasicine alkaloid from crude extract of *A. vasica*

Physical characteristics of vasicine alkaloid

Melting point

The melting point of the partial purified sample was measured according to [11]. in order to view the vasicine alkaloid purity.

Chemical characteristics

The method was done according to [12]. A few drops of modified Dragendroff's reagent were added to 5ml of leaves extract by methanol. The appearance of orange –red color indicated a positive result for alkaloid presence.

Inhibitory Assay

The method adopted was described by [13], with slight difference. briefly 0.2ml of the crude enzyme extract and different concentration of vasicine (0.2, 0.4, 0.6, 0.8, 1ml) of 10 % w/v of plant crude in 1.8 of 5 casein solution as reaction mixture, this reaction mixture was mixed and incubated at 37c for 10 minutes then reaction was stopped by adding 2ml of 5% tri-chloro acetic acid Protease assays was carried out and procedure was repeated without inhibitor.

3. Results and Discussion

Isolation and Identification of *Pseudomonas aeruginosa*

For isolation of *Pseudomonas* spp., 40 samples were collected from burning infections during the period From December to February in two hospitals (Baghdad Yarmouk Teaching Hospital and Medical City Hospital). The bacteria were obtained, and oxidase and catalase tests were used to isolate genus of pseudomonas.

Phenotypic test of *P. aeruginosa*

This study included thirty *P. aeruginosa* isolates identified using a variety of techniques, which are morphological and biochemical characterization. The result showed that *P. aeruginosa* produces green pigment and characteristic dour on cetrimide agar. *P. aeruginosa* reacted positively to catalase and oxidase tests and Simmon Citrate test, while it was negative for methyl red, Voges Proskauer and indole. These characteristics of the isolates were consistent with the description of typical *P. aeruginosa* according to (8; 16). Further biochemical tests were carried out to confirm characterization by using the API 20E system, which revealed that all 30 tested isolates belonged to the *P.aeruginosa*.

**Screening of *pseudomonas aeruginosa* Produce protease enzyme:
Semi-quantitative screening**

The bacterial susceptibility to the production of the protease on the skim milk agar was investigated Table-1.

Table 1- Hydrolysis ratio of Protein Skim milk- agar by *pseudomonas aeruginosa* that incubated at pH7.0 for 24 h. and at 37°C

number of isolates	Hydrolysis ratio (Diameter of clear zone) (Cm)

p15	11.8

Determination of optimal conditions for Proteins production:

Effect of medium compositions:

P. aeruginosa (p1) were grown in different media and enzyme production was measured. The results indicated that tryptic soya broth was the best production media for protease with a specific activity of 14.4U /mL, while Cassin-yeast extract medium was 13.1U/ mL and casein peptone medium showed less specific activity of protease 11.9U/ ml (Figure-2). The differences among the productivity of the enzymes in the cultivated media can be attributed to the variation in the quality of organic matter and its concentration in the food medium, such as protein and carbohydrates, as well as inorganic substances and their concentration as salts of calcium, phosphates, etc. and their role in stimulating the productivity of the bacterial enzyme. Complexity stimulates the production of protease from the microorganism better and more efficiently than the "simple nitrogen" source of the microorganism [15].

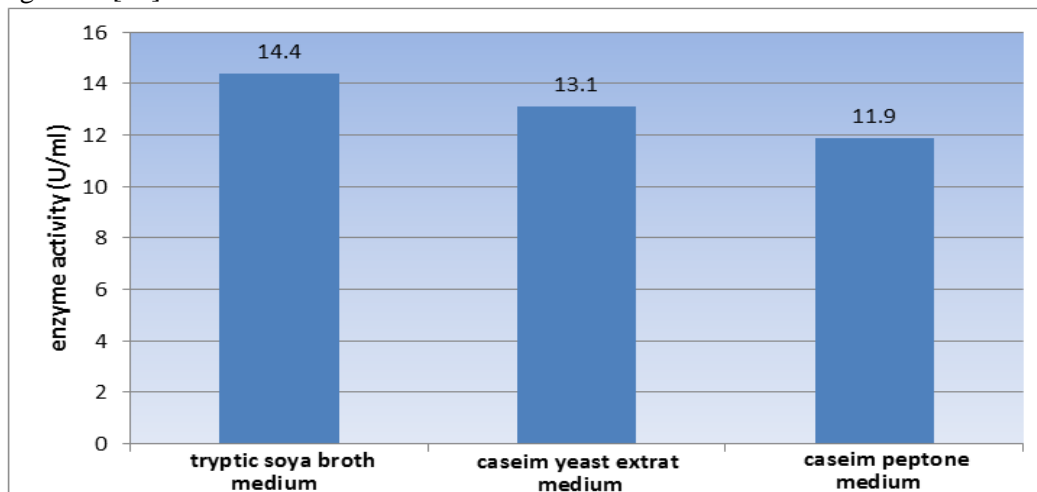

Figure 2-Protease production by *P. aeruginosa* P1 cultured on different media with incubation at 37°C and PH 8 for 24h.

Effect of pH media

For determination the effect of pH values on protease production, *P. aeruginosa* (P1) were cultured in tryptic soya broth with different pH values. The results showed that the enzyme was produced at pH ranged from 7.0 to 10.0, the maximum value of enzymatic activity was 15.5 that observed at pH 8.0 (Figure-3). The most important characteristic of microorganisms are their dependence on the extracellular pH for cell growth and enzyme production [16].

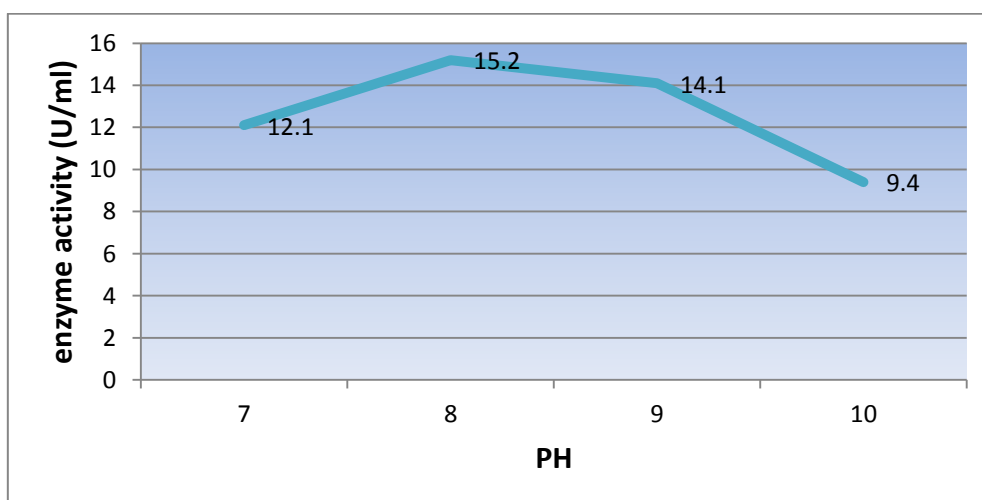

Figure 3-Protease production by *P. aeruginosa*P1 cultured in tryptic soya broth medium prepared at different pHs and incubated at 37°C. for 24h.

Effect of incubation temperature

Protease activity was evaluated at different incubation temperatures (30, 37, 40 and 50 °C). The results in (Figure-4) showed that the best temperature for Protease production by *p. aeruginosa*(P1) at 37 °C with a specific activity of 14.953U / ml (Fig. 3-3) and decreased productivity to 12.184 U / ml and 8.861U /ml at 30 ° C and 50 ° C respectively [17] reported that Temperature is one of the most important factors affecting the enzyme production and the temperature could regulate the synthesis and secretion of extracellular protease by microorganisms [18].

Figure 4-Protease production by *P. aeruginosa* P1 cultured in tryptic soya broth medium at pH 8.0 and incubated at different temperatures for 24 h.

Determination of optimum incubation time

Enzyme production was observed by *p. aeruginosa* (P1) after 24, 48 and 72 hrs. of incubation period that showed a maximum activity (15.276U / ml) was obtained after 48hrs. Then, the activity decreased with increasing incubation period (Figure -5). The protease is produced during logarithmic phase and reaches its maximum value at stationary phase [19]. In same time, attended that Enzyme production in culture medium did not change in the stationary phase [20].

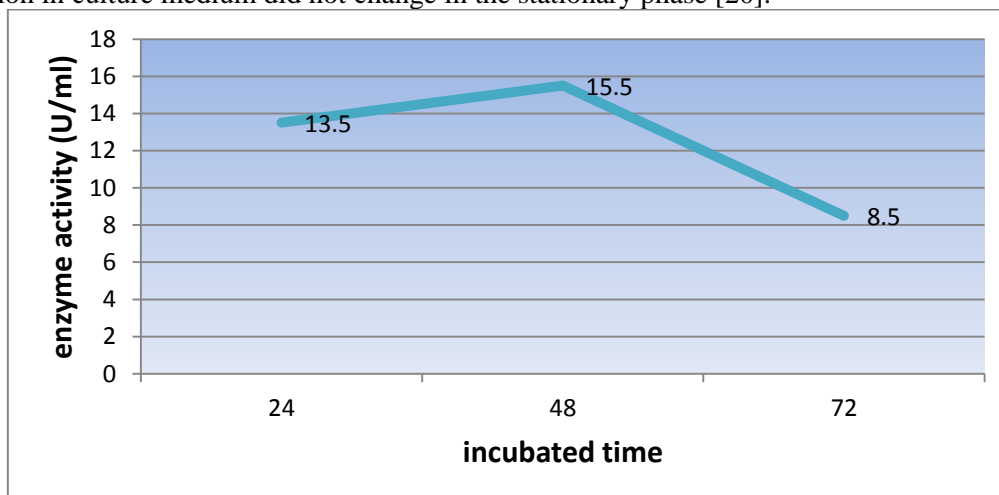

Figure 5-Protease production by *P. aeruginosa* P1 cultured on tryptic soya broth medium prepared at pH 8.0 and incubated at 37°C for different times.

Extraction of crude leaf extracts of *Adhatoda vasica*

The solvent that used for extraction of *A. vasica* was methanol 80%, because this concentration had a high extraction capacity with good polarity. This result was agreed with [21] and [22]. Also, the water polarity is high, but not all plant material can be dissolved and extracted with it. Therefore, methanol 80% consists of methanol and water at some time.

Estimation of extraction ratio for crude leaves extracts

The result of extraction ratio showed that was determined according to the percentage of concentrated crude extracts was reached 26 % [21].

Determination of the separated vasicine

According to the result, the percentage of separated vasicine about 1.6% and partial purified of vasicine alkaloids were about 0.6%. These results correspond to what the researchers obtained in [23]. The amount of vasicine may change and decrease during, un- flowering period of plant, while increase during flowering period, because this period is usually considered a vegetative defense period that requires an increase in quantity of vasicine alkaloid. In addition to all the above and when making simple economic calculations of the amount of total alkaloids obtained from the dry leaves that were extracted using methanol 80%, the percentage of isolated total alkaloids were (1.5%) and this means to get (15) grams of alkaloid from (1) Kg of dry leaves. These quantities of alkaloids obtained are good quantities compared to the quantities obtained by other researchers Isolation of alkaloids of *A. vasica* by H. Topenshaw and (2.1%) with pure alkaloids (0.8%) [24]. Also, the alkaloids were separated as pure alkaloid that was (1.3%) [10].

Determination of melting point for separated vasicine

The measurement of melting point was used as one of the basic and important tests for diagnosing the compounds for the characterization of vasicine alkaloid. The melting point was 210°C, which is agreement with those of other studies which referred to the range of vasicine melting points are 204-210°C [10]. This range may due to the flowering period and the purity of vasicine [24].

Biological activity of vasicine against protease activity

The activity of vasicine was tested against proteases activity. This was done by use different dilution of active compounds.

Test was done by identifying the range of response of enzyme to inhibition by vasicine and identify the range of enzyme inhibition depending on different dilutions of vasicine as shown in Table -3, that shows the response of the enzyme protease towards vasicine that extracted by using methanol 80% and hot D.W, at different concentration of these compounds. The mean response of protease inhibition was very high at the inhibitory dilution (4) is 1.2 U/ml, when the treated crude enzyme with vasicine.

Enzyme inhibition

Different concentrations (0.1, 0.2, 0.3, 0.4 and 0.5 ml) of active compounds (vasicine) were used as natural inhibitor for Protease (Table-4). Protease was measured before and after the addition of the compounds to know the effect of these compounds on the protease enzyme activity.

Table 4-Inhibitory effect of vasicine on the protease enzyme activity

NO.	Enzyme : vasicine (Concentration)	Enzyme activity (U/ml)
1	1:1	4.5
2	1:2	4.0
3	1:3	3.5
4	1:4	1.2
5	1:5	1.2

These results show the best ratio of (enzyme:extract) for inhibition of enzymatic activity of protease was 1:4 (0.2ml of enzyme treated with 0.8 ml of compound). The enzymatic activity decreases from 4.5 to 1.2 U/ml.

Table 5-Determination of inhibition activity of active compounds depending on its concentration

Active compounds	Concentration of active compounds(ml)	Inhibition activity %
Vasicine	0.2	70.96
	0.4	74.1
	0.6	77.4
	0.8	92.2
	1	92.2
