### Abstract

In this study we introduce the concepts of topological  $\Gamma$ -ring as generalization of Topological ring. We also present and study the concepts of topological  $\Gamma$ -ring, Homomorphism of topological  $\Gamma$ -ring, and compact of topological  $\Gamma$ -ring. The results have

confirmed that: if  $(G, +, \cdot, \Gamma)$  is a compact topological  $\Gamma$ -ring and  $f : (G, +, \cdot, \Gamma) \rightarrow (G^*, +', \cdot', \Gamma')$  epimorphism topological  $\Gamma$ -ring Then  $G^*$  is compact.

**Keywords:** topological  $\Gamma$ -ring, norm, homomorphism and compact.

## 1. INTRODUCTION

The concepts of topological ring is one of the most important topics in topological algebra. The objective of the concept of topological  $\Gamma$ -ring is to generalize the definition of topological ring.

The concept of  $\Gamma$ -ring was presented by Nobusawa 1964 in [1], and it was generalized by Barnes 1966 [2] as below:

Let  $M$  and  $\Gamma$  be two additive abelian groups. Suppose that there is a mapping from  $M \times \Gamma \times M \rightarrow M$ , the image of  $(a, \alpha, b)$  is denoted by  $a\alpha b$ ,  $a, b \in M$  and  $\alpha \in \Gamma$ , that satisfies the following for all  $a, b, c \in M$ ,  $\alpha, \beta \in \Gamma$ :

- i)  $(a+b)\alpha c = a\alpha c + b\alpha c$   
 $a(\alpha + \beta)c = a\alpha c + a\beta c$   
 $a\alpha(b+c) = a\alpha b + a\alpha c$
- ii)  $(\alpha\beta)c = \alpha(\beta c)$

Then  $M$  is called a  $\Gamma$ -ring., where every ring is a  $\Gamma$ -ring.  $M$  is said to be 2-torsion free if  $2a = 0$  implies  $a=0$  for all  $a \in M$ . Besides,  $M$  is called a prime  $\Gamma$ -ring if for all  $a, b \in M$ ,  $a\alpha\Gamma Mb = (0)$  implies either  $a=0$  or  $b=0$ , and  $M$  is called a semiprime if  $a\alpha\Gamma Ma = (0)$  with  $a \in M$  implies  $a=0$ . Note that every prime  $\Gamma$ -ring is obviously a semiprime [3], [4], [5-10].

In this paper we present the concept of topological  $\Gamma$ -ring as generalization of topological ring where we get every topological ring is topological  $\Gamma$ -ring. In general the converse is not true.

In this paper we introduce and study the concepts of topological  $\Gamma$ -ring, norm, homomorphism of topological  $\Gamma$ -ring some type of homomorphism kernel of homomorphism, and natural mapping as well as we present the compact of topological  $\Gamma$ -rings. We also prove that: If  $f: (G, +, \cdot, \Gamma) \rightarrow (G_1, +', \cdot', \Gamma')$  is homomorphism of topological  $\Gamma$ -ring  $G$  onto topological  $\Gamma$ -ring  $G_1$ , then

- 1) If  $I$  is an ideal of topological  $\Gamma$ -ring of  $G$  then  $f(I)$  is an ideal of topological  $\Gamma$ -ring  $G_1$ .
  - 2) If  $J$  is an ideal of topological  $\Gamma$ -ring of  $G_1$  then  $f^{-1}(J)$  is an ideal of topological  $\Gamma$ -ring  $G$ .
- The results have confirmed that: If  $f: (G, +, \cdot, \Gamma) \rightarrow (G^*, +', \cdot', \Gamma')$  is isomorphism topological  $\Gamma$ -ring from  $G$  into compact topological  $\Gamma$ -ring  $G^*$  then  $G$  is compact topological  $\Gamma$ -ring.

## 2. Topological $\Gamma$ -Rings:

Basic concepts related to the talked topic are given as follows with few important properties has been presented in the next section.

**Definition (2-1):** A topology  $\tau$  on a  $\Gamma$ -ring  $G$  is a topological  $\Gamma$ -ring, which is denoted by  $(G, +, \cdot, \tau)$ , iff:

- i)  $(m, n) \rightarrow m+n$  is continuous from  $G \times G$  into  $G$
- ii)  $(m, y)_\alpha \rightarrow m \alpha n$  is continuous from  $G \times G$  into  $G$
- iii)  $m \rightarrow -m$  is continuous from  $G \times G$  into  $G$

where  $G$  is given topology  $\tau$  and  $G \times G$  the Cartesian product topology determined by  $\tau$ .

**Example (2-2) :** Let  $G$  be any  $\Gamma$ -ring and  $\tau$  be discrete topology on  $G$  then  $(G, +, \cdot, \tau)$  is topology  $\Gamma$ -ring, which is called discrete topological  $\Gamma$ -ring

**Example (2-3) :** Let  $G$  be any  $\Gamma$ -ring and  $\tau$  be indiscrete topology on  $G$  then  $(G, +, \cdot, \tau)$  is topology  $\Gamma$ -ring, which is called indiscrete topological  $\Gamma$ -ring

**Example (2-4) :** Let  $R$  be the set of all real numbers and  $Q$  be the set of all rational numbers then  $R$  is  $Q$ -ring if  $\tau$  is usual topology on  $R$ , and then  $(R, +, \cdot, \tau)$  is topological  $Q$ -ring, which is called usual topological  $\Gamma$ -ring. By Definition (2.1),  $G=R$  and  $\Gamma=Q$ , also the operations  $+$ ,  $\cdot$  and  $-$  are continuous from  $R \times R$  into  $R$ .

Since every ring is  $\Gamma$ -ring, then we can get the following lemma

**Lemma (2-5):** Every topological ring is topological  $\Gamma$ -ring

The next example shows that the converse of Lemma (2-5) is not true in general.

Example (2-6): Let  $G = \left\{ \begin{pmatrix} a & b \\ c & d \\ s & t \end{pmatrix} : a, b, c, d, s, t \in Z \right\}$  and  $\Gamma = \left\{ \begin{pmatrix} x & y & z \\ w & u & v \end{pmatrix} : x, y, z, w, u, v \in Z \right\}$

then  $G$  is  $\Gamma$ -ring, if we define the discrete topology  $\tau$  on  $G$  then  $(G, +, \cdot, \tau)$  is topological  $\Gamma$ -ring. However  $(G, +, \cdot, \tau)$  is not topological ring.

**Definition (2-7):** A function  $N$  from a  $\Gamma$ -ring  $G$  into  $R^+ \cup \{0\}$  is a norm if the following conditions hold for all  $p, h \in G$  and  $\alpha \in \Gamma$ :

- 1)  $N(0) = 0$
- 2)  $N(p+h) \leq N(p) + N(h)$
- 3)  $N(-p) = N(p)$
- 4)  $N(p \alpha h) \leq N(p) \alpha N(h)$
- 5)  $N(p) = 0$  if and only if  $p = 0$ .

**Remark (2-8):** If  $N$  is a norm on a  $\Gamma$ -ring  $G$ , then  $d$  defined by  $d(p, h) = N(p-h)$  for all  $p, h \in G$  and  $\alpha \in \Gamma$ , is a metric. Indeed (1) and (5) imply that  $d(p, h) = 0$  iff  $p = h$ , (3) implies that  $d(p, h) = d(h, p)$ , and (2) yields the triangle inequality.

**Theorem (2.8):** Let  $N$  be a norm on a  $\Gamma$ -ring. The topology is given by the metric  $d$  which is defined by  $N$  is a  $\Gamma$ -ring topology

**Proof:** Let  $a, b, p, h \in G$  and  $\alpha \in \Gamma$ .

$$\begin{aligned} d(p+h, a+b) &= N((p+h)-(a+b)) \\ &= N((p-a)+(h-b)) \\ &\leq N(p-a) + N(h-b) \\ &= d(p,a) + d(h-b) \end{aligned}$$

Hence the definition (2-1) (1) holds, for all  $a, b \in G$

$$\begin{aligned} d(-p, -a) &= N(-p+a) \\ &= N(p-a) \\ &= d(p,a) \end{aligned}$$

By (3) of definition 2-6-hence the definition 2-1 (2) holds. Finally for all  $p, a \in G$

$$\begin{aligned} d(pah, a\alpha b) &= N((p-a) \alpha (h-b) + a\alpha(h-b) + (p-a)\alpha b) \\ &\leq N(p-a)\alpha N(h-b) + N(a)\alpha N(h-b) + N(p-a)\alpha N(b) \end{aligned}$$

Hence the definition 2-1 (3) holds, and the proof is finished

Let  $f$  be a partial function from the carrier of  $S$  to  $R$ , we recall that  $f$  is said to be uniformly continuous on  $X$  if and only if the following conditions are satisfied (i)  $X \subseteq \text{dom } f$ , and (ii) for every  $r$  such that  $0 < r$  there exists  $s$  such that  $0 < s$  and for all  $x_1, x_2$  such that  $x_1, x_2 \in X$  and  $\|x_1 - x_2\| < s$  holds  $|f(x_1) - f(x_2)| < r$ .) from  $G$  into  $R^+ \cup \{0\}$ .

**Theorem (2-9):** Let  $N$  be a norm on a  $\Gamma$ -ring  $G$ . for all  $p, h \in G$ , then  $|N(p) - N(h)| \leq N(p-h)$  ,and hence  $N$  is a uniformly continuous function .

**Proof:** 
$$\begin{aligned} N(p) &= N((p-h)+h) \\ &\leq N(p-h) + N(h) \end{aligned}$$

Then 
$$N(h) - N(p) \leq N(h - p) = N(p - h)$$

Therefore 
$$|N(p) - N(h)| \leq N(p - h)$$

Definition(2-10): Let  $(G, +, \cdot, \tau)$  be topological  $\Gamma$ -ring. A basis of  $\tau$  is a collection  $\mathcal{B}$  of  $\tau$   $U = \cup \{B: B \in \mathcal{B}_1\}$ .

**Theorem(2-11):** The Cartesian product of topological  $\Gamma$ -rings is a topological  $\Gamma$ -ring .

**Proof:** Let  $(G, +, \cdot, \tau)$  and  $(G_1, +, \cdot, \tau_1)$  are two topological spaces and  $\mathcal{B}$  be a basis of  $\tau$  and  $\mathcal{C}$  be a basis for  $\tau_1$  then

$$\mathcal{H} = \{B \times C: B \in \mathcal{B} \text{ and } C \in \mathcal{C}\}$$
 is a basis for the product topology  $(G \times G_1, +, \cdot, \mathcal{W})$

Let  $(x, y)$  be any point of  $G \times G_1$  and  $\mathcal{N}$  be a neighborhood of  $(x, y)$

Since  $E = \{X \times Y: X \in \tau \text{ and } Y \in \tau_1\}$  is a basis for  $\mathcal{W}$  there exists a member

$$X \times Y \text{ of } E \text{ such that } (x, y) \in X \times Y \subseteq \mathcal{N} \quad \dots(1)$$

Since  $X$  is  $\tau$ -open and  $\mathcal{B}$  is a basis for  $\tau$  there exists some  $B \in \mathcal{B}$  such that

$x \in B \subseteq X$ . Similarly there exists some  $C \in \mathcal{C}$  such that  $y \in C \subseteq Y$ . It follows that

$$(x, y) \in B \times C \subseteq X \times Y \quad \dots(2)$$

Hence from (1) and (2) , we get  $(x, y) \in B \times C \subseteq \mathcal{N}$ . This implies that  $\mathcal{H}$  is basis for  $G \times G_1$

### 3. HOMOMORPHISM of TOPOLOGICAL $\Gamma$ - RINGS:

We introduce and study in this section the following concepts subtopological  $\Gamma$ -ring, ideal of topological  $\Gamma$ -ring, and homomorphism of topological  $\Gamma$ -ring as well as some properties of them are given.

**Definition (3-1) :** Let  $(G, +, \cdot, T)$  be topological  $\Gamma$ -ring a subring  $S$  of topological  $\Gamma$ - ring is called topological  $\Gamma$ -subring ( or called subtopological  $\Gamma$ -ring) denoted by  $(S, +, \cdot, T_S)$  where  $A_S \in T_S$   $A_S = A \cap S$ , for all  $A \in T$ .

Every topological  $\Gamma$ -ring  $(G, +, \cdot, T)$  have two topologica  $\Gamma$ -subrings  $(0)$  and  $G$  itself which is called trivial topologica  $\Gamma$ -subrings. Any topological  $\Gamma$ -subring except trivial is called proper topological  $\Gamma$ -subring.

**Definition (3-2):** A topological  $\Gamma$ -subring  $(I, +, \cdot, T)$  of topological  $\Gamma$ -ring  $(G, +, \cdot, T)$  is called an ideal of  $(G, +, \cdot, T)$  if  $I\Gamma G \subseteq I$  and  $G\Gamma I \subseteq I$ .

**Definition (3-3):** Let  $(G, +, \cdot, T)$  and  $(G_1, +', \cdot', T^*)$  be two topological  $\Gamma$ - rings.

A map  $f: (G, +, \cdot, T) \rightarrow (G_1, +', \cdot', T^*)$  is called homomorphism of topological  $\Gamma$ -ring , if

$f:(G, T) \rightarrow (G_1, T^*)$  is continuous and  $f$  satisfies:

$f(p + h) = f(p) + f(h)$ , and  $f(p \cdot \alpha \cdot h) = f(p) \cdot \alpha \cdot f(h)$ , for all  $p, h \in G$  and  $\alpha \in \Gamma$ .

An epimorphism topological  $\Gamma$ -ring if  $f$  is continuous map and epimorphism  $\Gamma$ -ring, a monomorphism topological  $\Gamma$ -ring is a continuous mapping and monomorphism  $\Gamma$ -ring. An isomorphism topological  $\Gamma$ -ring is a homeomorphism topological map (A mapping  $f:(X, T_X) \rightarrow (Y, T_Y)$  is called homeomorphism if  $f$  is 1-1 and onto also  $f$  and  $f^{-1}$  are continuous) and isomorphic  $\Gamma$ -rings, an automorphism topological  $\Gamma$ -ring is a continuous mapping and automorphism  $\Gamma$ -ring.

**Lemma (3-4):** Let  $f: (G, +, \cdot, \Gamma, T) \rightarrow (G_1, +', \cdot', \Gamma', T^*)$  be isomorphism of topological  $\Gamma$ -ring then:

1) If  $S$  is a subtopological  $\Gamma$ -ring of  $G$ , then  $f(S)$  is a subtopological  $\Gamma$ -ring of  $G_1$ .

2) If  $E$  is a subtopological  $\Gamma$ -ring of  $G_1$ , then  $f^{-1}(E)$  is a subtopological  $\Gamma$ -ring of  $G$ .

**proof:** We prove (2) and (1) by using the same technical

2) By assumption we get

$(E, +', \cdot', \Gamma', T^*_E)$  is subtopological  $\Gamma$ -ring of  $(G_1, +', \cdot', \Gamma', T^*)$

Since  $f$  is homomorphism

Therefore for all  $E \in T^*_E$  then  $f^{-1}(E) \in T_{f^{-1}(S_E)}$

Now, let  $p, h \in f^{-1}(E)$  then  $f(p), f(h) \in E$  and  $\alpha \in \Gamma$ .

i)  $f(p-h) = f(p) - f(h)$

Since  $f(p), f(h) \in E$  and  $E$  is subtopological  $\Gamma$ -ring then  $f(p) - f(h) \in E$ , and hence

$p-h \in f^{-1}(E)$

ii)  $f(p \cdot \alpha \cdot h) = f(p) \cdot \alpha \cdot f(h)$

Since  $f(p), f(h) \in E, \alpha \in \Gamma$  and  $E$  is subtopological  $\Gamma$ -ring then  $f(p) \cdot \alpha \cdot f(h) \in E$  hence

$p \cdot \alpha \cdot h \in f^{-1}(E)$ . Therefore  $f^{-1}(E)$  is subtopological  $\Gamma$ -ring.

**Lemma (3-5):** If  $f: (G, +, \cdot, \Gamma, T) \rightarrow (G_1, +', \cdot', \Gamma', T^*)$  is homomorphism of topological  $\Gamma$ -ring  $G$  onto topological  $\Gamma$ -ring  $G_1$ , then

1) If  $I$  is an ideal of topological  $\Gamma$ -ring of  $G$  then  $f(I)$  is an ideal of topological  $\Gamma$ -ring  $G_1$ .

2) If  $J$  is an ideal of topological  $\Gamma$ -ring of  $G_1$  then  $f^{-1}(J)$  is an ideal of topological  $\Gamma$ -ring  $G$ .

**Proof: 1) (i)** By theorem (3-4)  $f(I)$  is a subtopological  $\Gamma$ -ring

(i.e.  $f(I) \neq \emptyset$  and  $a-b \in f(I), \forall a, b \in f(I)$ )

(ii) Let  $r \in G_1$  and for all  $a \in f(I)$ , and  $\alpha \in \Gamma$ .

T.P.  $a \cdot \alpha \cdot r' \in f(I)$  and  $r' \cdot \alpha \cdot a \in f(I)$

$\because f$  is onto, then  $\exists r \in G$  s.t.  $r' = f(r) \dots \dots *$

and  $\exists x \in I$  s.t.  $a = f(x) \dots \dots **$

since,  $r \in R, x \in I$  and since  $I$  is an ideal of a ring

$\Rightarrow x \cdot \alpha \cdot r \in I$  and  $r \cdot \alpha \cdot x \in I$

$\Rightarrow f(x \cdot \alpha \cdot r) \in f(I)$  and  $f(r \cdot \alpha \cdot x) \in f(I)$

$\Rightarrow f(x) \cdot \alpha \cdot f(r) \in f(I)$  and  $f(r) \cdot \alpha \cdot f(x) \in f(I)$

$\Rightarrow a \cdot \alpha \cdot r' \in f(I)$  and  $r' \cdot \alpha \cdot a \in f(I)$

Therefore,  $f(I)$  is an ideal of topological  $\Gamma$ -ring  $G_1$ .

2) By using the same technic of (1) we get the require result.

**Theorem (3-6):** If  $f: (M, +, \cdot, \Gamma, T) \rightarrow (M_1, +', \cdot', \Gamma', T_1)$  is homomorphism of topological  $\Gamma$ -ring  $M$  onto topological  $\Gamma$ -ring  $M_1$  then every homomorphism image of

1) If  $M$  is commutative topological  $\Gamma$ -ring then  $M_1$  is a commutative topological  $\Gamma$ -ring.

2) If  $M$  is topological  $\Gamma$ -ring with identity  $1$  then  $M_1$  is a topological  $\Gamma$ -ring with identity  $1'$ .

**Proof:** Since  $f$  is a homomorphism from a topological  $\Gamma$ -ring  $(M, +, \cdot, \Gamma, T)$  into a topological  $\Gamma$ -ring  $(M_1, +', \cdot', \Gamma', T_1)$ .

1) Suppose that  $(M, +, \cdot, \Gamma, T)$  be a commutative topological  $\Gamma$ -ring

Let  $a, b \in M_1, \alpha \in \Gamma$  and since  $f$  is onto,

Then ,  $\exists x, y \in M$  , s.t. ,  $a = f(x)$  and  $b = f(y)$

$$\begin{aligned} \therefore a \alpha b &= f(x)\alpha f(y) = f(x \alpha y) \quad (\text{since } f \text{ is homo.}) \\ &= f(y \alpha x) \quad (\text{since } M \text{ is a comm. topological } \Gamma\text{-ring}) \\ &= f(y) \cdot f(x) \quad (\text{since } f \text{ is homo.}) \\ &= b \alpha a \end{aligned}$$

Hence ,  $M_1$  is a commutative topological  $\Gamma$ -ring

2) Suppose that  $M$  be a topological  $\Gamma$ -ring with identity

Let  $a \in M_1$  since  $f$  is onto therefore  $\exists x \in M$  s.t.  $a=f(x)$

$$x \alpha 1 = 1 \alpha x = x, \forall x \in M, \alpha \in \Gamma.$$

$$\Rightarrow f(x \alpha 1) = f(1 \alpha x) = f(x)$$

$$\Rightarrow f(x) \alpha f(1) = f(1) \alpha f(x) = f(x) \quad [f \text{ is homomorphism}]$$

$$\Rightarrow a \alpha 1' = 1' \alpha a = a, \text{ for all } a \in M_1.$$

Thus,  $M_1$  is a topological  $\Gamma$ -ring with identity  $1'$ .

**Definition (3-7):** Let  $f : (M, +, \cdot, \Gamma) \rightarrow (M_1, +', \cdot', \Gamma_1)$  is homomorphism of topological  $\Gamma$ -ring  $s$ , then the kernel of  $f$  is denoted by  $\ker.(f)$ , and it is defined by

$$\ker.(f) = \{m \in M : f(m) = 0_{M_1}\}$$

**Lemma (3-8):** If  $f : (G, +, \cdot, \Gamma) \rightarrow (G^*, +', \cdot', \Gamma^*)$  is homomorphism of topological  $\Gamma$ -ring  $G$  into topological  $\Gamma$ -ring  $G^*$ , then the  $\ker.(f)$  is an ideal of topological  $\Gamma$ -ring  $G$ .

**Proof:** 1) Let  $p, h \in \ker.(f)$  and  $f$  is homomorphism of topological  $\Gamma$ -ring ,

$$\text{we get } f(p - h) = f(p) - f(h) = 0_{G^*}$$

then  $p-h \in \ker.(f)$

2) Let  $p, h \in \ker.(f), \alpha \in \Gamma$  and  $f$  is homomorphism of topological  $\Gamma$ -ring

$$\text{we get } f(p \alpha h) = f(p) \alpha f(h) = 0_{G^*}$$

then  $p \alpha h \in \ker.(f)$

Hence  $\ker.(f)$  is an ideal of topological  $\Gamma$ -ring  $(G, +, \cdot, \Gamma)$ .

**Theorem (3-9):** If  $f$  is homomorphism of topological  $\Gamma$ -ring  $(G, +, \cdot, \Gamma)$  into topological  $\Gamma$ -ring  $(G^*, +', \cdot', \Gamma^*)$  then  $f$  is one-one iff  $\ker.(f) = \{0\}$ .

**Proof :** Suppose that  $\ker.(f) = \{0\}$

$$\text{Let } r, e \in G \text{ s.t. } , f(r) = f(e) \Rightarrow f(r) - f(e) = \hat{0}$$

$$f(r - e) = \hat{0} \quad (f \text{ is homo.})$$

$$r - e \in \text{Ker.} f$$

$$\text{But } , \text{Ker.} f = \{0\} \Rightarrow r - e = 0 \Rightarrow r = e$$

Suppose that  $f$  is one to one

$$\text{Let } r \in \text{Ker}(f) \Rightarrow f(r) = \hat{0} \text{ and since } f(0) = \hat{0}, \text{ therefore } f(r) = f(0)$$

$$\text{Since } , f \text{ is one to one } \Rightarrow r = 0 \Rightarrow r \in \{0\} \Rightarrow \text{Ker}(f) \subseteq \{0\}.$$

$$\text{Since } f(0) = \hat{0}$$

$$\Rightarrow 0 \in \text{Ker.} f \Rightarrow \{0\} \subseteq \text{Ker}(f)$$

$$\text{Ker}(f) = \{0\} .$$

**Theorem (3-10):** If  $(I, +, \cdot)$  is an ideal of the topological  $\Gamma$ -ring  $(M, +, \cdot, \Gamma)$  then the natural map is a homomorphism from a topological  $\Gamma$ -ring  $M$  to the topological quotient  $\Gamma$ -ring  $(M/I, +, \cdot, \Gamma)$  with kernel equal to  $I$ .

**Proof :** Let  $m, n \in M, \alpha \in \Gamma$

$$1- \text{nat}_I(m + n) = (m + n) + I = (m + I) + (n + I) = \text{nat}_I(m) + \text{nat}_I(n)$$

$$2- \text{nat}_I(m \alpha n) = (m \alpha n) + I = (m + I) \alpha (n + I) = \text{nat}_I(m) \alpha \text{nat}_I(n)$$

$\text{nat}_I : (M, \Gamma) \rightarrow (M/I, \Gamma)$  is continuous map since every open set  $V$  in  $M/I$  then  $\text{nat}_I^{-1}(V)$  is open in  $M$ .

Hence  $\text{nat}_I$  is homomorphism

Now, to prove  $\text{nat}_I$  is on to

$$\forall m + I \in R/I \Rightarrow \exists m \in R \text{ s.t. } \text{nat}_I(m) = m + I$$

$\therefore \text{nat}_I$  is onto.

$$\begin{aligned} \text{Ker.}(\text{nat}_I) &= \{ m \in R : \text{nat}_I(m) = 0 + I \} \\ &= \{ m \in R : m + I = 0 + I \} \\ &= \{ m \in R : m + I = I \} \\ &= \{ m \in R : m \in I \} \\ &= I \end{aligned}$$

**Theorem (3-11):** If  $f$  is homomorphism of topological  $\Gamma$ -ring  $(G, +, \cdot, T)$  into topological  $\Gamma$ -ring  $(G^*, +', \cdot', T^*)$  then  $M/\text{ker.}(f)$  is isomorphic to topological  $\Gamma$ -ring  $G^*$ .

**Proof:** We define a map  $g$  from topological  $\Gamma$ -ring  $(M/\text{ker.}(f), +, \cdot, T)$  into topological  $\Gamma$ -ring  $(G^*, +', \cdot', T^*)$  by  $g(E + \text{ker.}(f)) = f(E)$ , for all  $E \in G$

It's clear that  $g$  is well define and one to one.

Now, to show  $g$  is homomorphism.

Let  $p \in \text{ker.}(f)$ ,  $h \in \text{ker.}(f) \in M/\text{ker.}(f)$

$$g((p + \text{ker.}(f)) + (h + \text{ker.}(f))) = f(p + h) = f(p) + f(h) = g(p + \text{ker.}(f)) + g(h + \text{ker.}(f))$$

$$g(((p + \text{ker.}(f)) \alpha (h + \text{ker.}(f)))) = f(p \alpha h) = f(p) \alpha f(h) = g(p + \text{ker.}(f)) \alpha g(h + \text{ker.}(f))$$

To prove  $g$  is onto.

Let  $E \in G$ ,  $E + \text{ker.}(f) \in M/\text{ker.}(f)$  where  $m \in G$ , since  $f$  is onto then there exist  $f(E) \in G^*$  such that  $g(E + \text{ker.}(f)) = f(E)$ . hence  $g$  is onto.

Hence  $g$  is isomorphism  $\Gamma$ -ring.

Now, since  $f$  is continuous therefore  $g$  is continuous.

Let  $U$  be an open set in  $G/\text{ker.}(f)$

Since  $g(E + \text{ker.}(f)) = f(E)$  and  $f$  is continuous, so it  $g^{-1}$  is continuous

$g^{-1}: G^* \rightarrow G/\text{ker.}(f)$  and  $f$  is continuous then  $g^{-1}$  is continuous.

Hence the topological  $\Gamma$ -ring  $G/\text{ker.}(f)$  is isomorphic topological  $\Gamma$ -ring to  $G^*$ .

**Theorem (3-12):** If  $M$  is a topological  $\Gamma$ -ring let  $S$  be a subring, and  $I$  be an ideal of  $M$ . Then:

(1)  $S + I = \{ s + a : s \in S, a \in I \}$  is a topological subring of  $M$ ,

(2)  $S \cap I$  is an ideal of  $S$ .

(3)  $(S + I)/I$  is isomorphic topological  $\Gamma$ -ring to  $S/(S \cap I)$ .

**Proof :** It is clear so that the proof is omitted.

**Theorem (3-13):** Let  $(M, +, \cdot, T)$  be a topological  $\Gamma$ -ring and let  $J \subset I$  be ideals of  $M$ . Then  $I/J$  is an ideal of  $M/J$  and

$$\frac{M/J}{I/J} \cong M/J$$

**Proof:** Since  $I$  and  $J$  are ideals, they are non-empty and so that  $I/J = \{ a + J : a \in I \}$  is also non-empty. Let  $a_1, a_2 \in I$ ;  $m \in M$ , and  $\alpha \in \Gamma$ . By definition of addition, and multiplication of the cosets, we have  $(a_1 + J) + (a_2 + J) = (a_1 + a_2) + J$ ,  $(m + J)\alpha(a_1 + J) = m\alpha a_1 + J$ , and  $(a_1 + J)\alpha(m + J) = a_1\alpha m + J$ . Since  $I$  is an ideal,  $a_1 + a_2$ ,  $m\alpha a_1$ , and  $a_1\alpha m$  are contained in  $I$  so that  $I/J$  is an ideal of  $M/J$ . Let  $\varphi: M/J \rightarrow M/I$  that sends  $m + J$  to  $m + I$ . It is clear that this is a well-defined surjective homomorphism with kernel equal to  $I/J$ , and  $\varphi$  is also open map. Then  $(M/J)/(I/J)$  is isomorphism topological  $\Gamma$ -ring to  $M/I$  by the first isomorphism theorem.

#### 4. COPMACT TOPOLOGICAL $\Gamma$ - RINGS:

**Definition (4-1):** Let  $(G, +, \cdot, J)$  be a topological  $\Gamma$ -ring, the family  $\{ G_i \in J: (G_i, +, \cdot, J_i) \}$  is a proper subrings of  $G$ , for all  $i \in \Lambda$  is a cover topological  $\Gamma$ -ring of  $(G, +, \cdot, J)$  if  $G = \bigcup_{i \in \Lambda} G_i$ .

**Definition (4-2):** Let  $(G, +, \cdot, J)$  be topological  $\Gamma$ -ring then  $(G, +, \cdot, J)$  is compact topological  $\Gamma$ -ring if for every cover topological rings of  $(G, +, \cdot, J)$  there is a finite sub cover topological

**Example(4-3):** Every finite topological  $\Gamma$ -ring is compact topological  $\Gamma$ -ring.

**Theorem (4-4):** If  $f: (G, +, \cdot, J) \rightarrow (G^*, +', \cdot', T^*)$  is isomorphism topological  $\Gamma$ -ring from  $G$  to compact topological  $\Gamma$ -ring  $G^*$  then  $G$  is compact topological  $\Gamma$ -ring. **Proof :** Suppose that  $S = \{$

$G_i \in \mathcal{J}$ :  $(G_i, +, \cdot)$  is a proper subring of  $G$ , for all  $i \in \Lambda$  is a cover topological  $\Gamma$ -ring of  $(G, +, \cdot, \mathcal{J})$ . That means  $G = \bigcup_{i \in \Lambda} G_i$ . Therefore  $f(G) = G^* = \bigcup_{i \in \Lambda} f(G_i)$ , where  $f(G_i) \in T^*$ .

Since  $G^*$  is compact, it follows that there is a finite subcover  $\mathcal{H} \subseteq \mathcal{S}$

Such that  $G^* \subseteq \mathcal{H}$

Since  $f$  is isomorphism we get  $G = f^{-1}(\mathcal{H})$ , where  $f^{-1}(\mathcal{H})$  is a finite subcover of  $G$ .

**Theorem (4-5):** Every closed subset of a compact topological  $\Gamma$ -ring space is compact.

**Proof:** Let  $B$  be a closed subset of the compact topological  $\Gamma$ -ring  $(G, +, \cdot, \mathcal{J})$ .

Let  $D^* = \{G_i \in \mathcal{J} : (G_i, +, \cdot)$  is a proper subring of  $G$ , for all  $i \in \Lambda\}$  be a cover topological  $\Gamma$ -ring of  $D^*$ . Since  $B$  is closed then  $G-B$  is open, and

$C = D^* \cup (G-B)$  is an open cover of  $G$ . Since  $G$  is compact topological ring, it has a finite subcover, containing only finitely many members  $G_1, \dots, G_n$  of  $D^*$  and may contain  $G-B$ . Since  $G = (G-B) \cup \bigcup_{i=1}^n G_i$  it follows that  $B \subseteq \bigcup_{i=1}^n G_i$  and  $D^*$  has a finite subcover.

**Theorem (4-6):** If  $(G, +, \cdot, \mathcal{J})$  is a compact topological  $\Gamma$ -ring, and

$f : (G, +, \cdot, \mathcal{J}) \rightarrow (G^*, +', \cdot', T^*)$  epimorphism topological  $\Gamma$ -ring, then  $G^*$  is compact.

**Proof:** Assume that  $\mathcal{S}^* = \{G^*_i \in T^* : (G^*_i, +', \cdot')$  is a proper subring of  $G^*$ , for all  $i \in \Lambda\}$  is a cover topological  $\Gamma$ -ring of  $\mathcal{S}^*$  that is  $G^* = \bigcup_{i \in \Lambda} G^*_i$

Since  $f$  is epimorphism topological  $\Gamma$ -ring this implies that

$G = \bigcup_{i \in \Lambda} f^{-1}(G^*_i)$ , where  $f^{-1}(G^*_i) \in \mathcal{J}$

Since  $G$  is compact topological  $\Gamma$ -ring, this gives  $G = \bigcup_{i=1}^n f^{-1}(G^*_i)$ . Hence  $f$  is epimorphism topological  $\Gamma$ -ring  $G^* = \bigcup_{i=1}^n G^*_i$ .

Thus  $G^*$  is compact topological  $\Gamma$ -ring

**Acknowledgements:** The author wishes to express his gratitude to the reviewers for their insightful suggestions that improved the paper's presentation and for volunteering their time to assist in its publication.

**Financial support:** This study did not receive any financial support from any organisation.
