Abstract

In this study, the concept of fuzzy α -topological vector space is introduced by using the concept fuzzy α -open set, some properties of fuzzy α -topological vector spaces are proved. We also show that the space is T_2 -space iff every singleton set is fuzzy α -closed. Finally, the convex property and its relation with the interior points are discussed.

Keywords: Topological Vector Space, Fuzzy α -Topological Vector Space, Fuzzy T_2 -space and Extremely points.

الفضاءات التبولوجية المتجهة الضبابية نوع الفا

الخلاصه

تناولت هذه الدراسة تعريف الفضاءات التبولوجية المتجهة الضبابية نوع الفا و دراسة خصائصها , كما تم اثبات ان الفضاء يكون منفصلا ضبابيا اذا كانت كل مجموعة منفردة مغلقة ضبابيا , وتم مناقشة الخاصية الجبرية (التحدب) وعلاقتها بالنقاط الداخلية للمجموعات الموجودة في الفضاء المدروس.

Introduction and Preliminaries:

The aim of the study is to define the notation of fuzzy α -topological vector space in the term of fuzzy set. The fuzzy concept has used in many branches of mathematics since 1965. The introduction of fuzzy sets is done by Zadeh [1]. The theories of fuzzy topological vector spaces are introduced and developed by A.K.Katsaras [2],[3], and are generalized by many authors as in [4],[5]. We consider it in terms of fuzzy α -open set by the sense of Bin Shanna, [6]. A subset A of a topological space X is called fuzzy α -open (fa-open) if $A \subset (\text{Int}(Cl(\text{Int}(A))))$ [7], while a complement for fa-open set is called fuzzy α -closed (fa-closed). The fuzzy α -closure of A that subset of X is represented by $Cl_\alpha(A)$ which is intersection for all fa-closed subsets on X containing A . Recall that the subset $U \subset X$ is called fa-open neighborhood for x if there is a fa-open set A with $x \in A \subset U$. The point x for a subset A is said to be fa-interior point on A which is denoted by $\text{Int}_\alpha(A)$, if there is fa-open subset U , $x \in U$, and $U \subset A$. A function $f: X \rightarrow Y$ is called fa-irresolute continuous if an inverse image for each fa-open subset in Y is fa-open on X where X and Y is a fuzzy topological spaces [8]. Also, a mapping $f: X \rightarrow Y$ is called fa-irresolute continuous at point x on X if for all fa-open

*Email: suhadkhamid@gmail.com

subset V on Y contained $f(x)$, there is a fa -open subset U with $x \in U$ satisfy $f(U)$ is subset of V [8]. A function f from a fuzzy topological space X to Y is called fa -open function if the image for each fa -open subset of X is fa -open set in Y . Moreover, the notion of fa -homeomorphism [8] that defines a mapping f from X to Y is called fa -homeomorphism if it's bijective, both f and f^{-1} are fa -irresolute. The separation axiom and the compactness property are discussed.

1. Fuzzy α - Topological Vector Space (F α TVS).

Definition 1.1: A fuzzy α - topological vector space is a vector space V over a field F with a fuzzy topology τ such that the two functions :

- (a) The vector addition map $S: X \times X \rightarrow X$
- (b) The multiplication by scalar map $M: F \times X \rightarrow X$

Are fuzzy α - irresolute continuous. For each $x \in X$ the mapping $T_x: X \rightarrow X$ which is defined by $T_x(y) = y + x$, and the mapping $M_\lambda: X \rightarrow X$ that is defined by $M_\lambda(x) = \lambda \cdot x$ are called the translation, and multiplication, respectively.

We refer to the collection of fa -neighborhoods for $x \in X$, by N_x , and we denote the set of fa -neighborhoods of zero vector space 0 of X by N_0 . A subset A of a topological spaces (X, τ) is called sp -open if $A \subset \text{cl}(\text{int}(\text{cl}(A)))$ [8].

Lemma 1.2[9]: Let A be a sp -open (α -open, fa -open) subset of a topological space X , and B be any open subset of X , then the set $A \cap B$ is sp -open (α -open, fa -open, respectively) set.

Lemma 1.3[9]: Let $f: X \rightarrow Y$ be sp -irresolute mapping where X and Y are topological spaces, so that for sp -neighborhood V for $f(x)$, there sp -neighborhood U of x satisfies $f(U) \subseteq V$.

Theorem 1.4: Let X be F α TVS, the following statements hold.

- a. If $U \in N_x$, and V is a neighborhood for x in X , then $U \cap V \in N_x$.
- b. If $U \in N_0$, then $\lambda U \in N_0$ for a non-zero element $\lambda \in R$.
- c. If $U \in N_0$, then $x + U \in N_x$.

Proof: a) Suppose that U is fa -neighborhood of x , and V is a neighborhood for x , then there exists a fa -open subset A and an open set B s.t $x \in A \subset U$ and $x \in B \subset V$.

Then $x \in A \cap B \subseteq U \cap V$ and by Lemma 1.2, $A \cap B$ is fa -open. So that $A \cap B$ is a fa -neighborhood for x . To prove (b) and (c), let U is fa -neighborhood for zero since $S: (x, y)$ is fa -irresolute, we define the function $T_x: X \rightarrow X$ by $T_x(y) = y + x$. Therefore $T_x(y) = S_x(x, y)$, $T_x(y)$ is fa -irresolute also $T_x^{-1}(y) = S_x(x, -y)$ is also fa -irresolute (from the definition of addition), thus T_x is fa -homeomorphism, by lemma 1.3 for a fa -neighborhood U for zero, there fa -neighborhood $U + x$ for a point x .

Definition 1.5[10]: The subset A on the vector spaces X is called balanced if $\lambda A \subseteq A$ for $|\lambda| \leq 1$ and absorbing if every x belongs to X , there is $\varepsilon > 0$ such that $\lambda x \in A$ for $|\lambda| \leq \varepsilon$. It is called absolutely convex if the subset both balanced and convex.

Theorem 1.6: Let X be an F α TVS, then

- (a) Every fa -neighborhood U of 0 is absorbing.
- (b) For a fa -neighborhood U of 0 there exists a balanced $V \in N_0$ satisfy that $V \subseteq U$.

Proof: (a) Suppose U be a fa -neighborhood for 0 , then there exists a fa -open subset $U_1 \in N_0(X)$ such that $U_1 \subseteq U$, since the scalar multiplication map M_λ is fa -irresolute, so that there exists fa -neighborhood of 0 (V_1, V_2) satisfies that $M_\lambda(V_1 \times V_2) \subseteq U_1$. Let a set V_1 contains an open interval $(-\varepsilon, \varepsilon)$, therefore $tx \in U_1 \forall t \in (-\varepsilon, \varepsilon)$ and for all $x \in V_2$. This leads to U_1 which is absorbing.

(b). The map of multiplication $M_\lambda: R \times X \rightarrow X$ is fa -irresolute then for every fa -neighborhood U of 0 in X there exists fa -neighborhood of 0 , $M_\lambda(V) \subseteq U$, then there exists $\varepsilon > 0$, $V = V_1 \times V_2$, $(-\varepsilon, \varepsilon) \subseteq V_1$, V_1 is a fa -neighborhood for 0 on R ,

V_2 is fa -neighborhood of 0 in X . Let $W = \bigcup_{|t| < \varepsilon} tV_2$, tV_2 be fa -neighborhood of 0 from theorem 1.4, for $t \neq 0$ and $tV_2 \subseteq U$ for $|t| < \varepsilon$. Now we need to prove that W is balanced. If $r < 1$, so $rW = \bigcup_{|t| < \varepsilon} (rt)V_2$ and $|rt| < \varepsilon$, it implies that $rW = \bigcup_{|s| < \varepsilon} sV_2 \subseteq W$, where $s = rt$, thus W is balanced.

Theorem 1.7 : Let. X be a FaTVS . If $A \subseteq X$, so $\text{Cl}_{\text{fa}}(A) = \bigcap (A+U)$. In particular $\text{Cl}_{\text{fa}}(A) \subseteq A+U, \forall U$ belongs to N_0 .

Proof: Let. $x \in \text{Cl}_{\text{fa}}(A)$, U be a fa -neighborhood of 0 then by theorem 1.6(b) V is the balanced neighborhood for zero s.t. $(V \subseteq U)$, so $x+V$ fa -neighborhood for x and $x \in \text{Cl}_{\text{fa}}(A)$, then $(x+V) \cap A \neq \emptyset$, that implies $x \in A+V$. Since V is balanced, $A+V$ equal to $A+V$, then $x \in A+V$ subset of $A+U$, hence $\text{Cl}_{\text{fa}}(A) \subseteq \bigcap (A+U)$. Conversely if $x \in \text{Cl}_{\text{fa}}(A)$, so that there balanced neighborhood U for zero satisfy that $(x+U) \cap A = \emptyset$, so that $x \notin A+U = A+U$.

Theorem 1.8: Let. X be a FaTVS . Then ,

(a) Every $U \in N_0, \exists V \in N_0$ satisfy $V+V \subseteq U$.

(b) For every $U \in N_0$, there is a fa -closed balanced $V \in N_0$ satisfy that $V \subseteq U$.

Proof: (a) Assume that $U \in N_0(X)$, since the map $S: X \times X \rightarrow X$ is fa -irresolute, then there are fa -neighborhoods for 0 say V_1 and V_2 satisfy $S(V_1, V_2) \subseteq U$, that means $V_1+V_2 \subseteq U$, set $V = V_1 \cap V_2$ which implies $V+V \subseteq V_1+V_2 \subseteq U$.

(b) Assume that U is fa -neighborhood of 0 on X , by part (a) there is fa -neighborhood V for zero with $V+V \subseteq U$. Now from Part (b) of Theorem 1.6, there exists a neighborhood W for 0 which is balanced s.t. $W \subseteq V$. Now from theorem 1.7 the $\text{Cl}_{\text{fa}}(W) \subseteq W+V$ and $\text{Cl}_{\text{fa}}(W) \subseteq W+V \subseteq V+V \subseteq U$. This shows that U contains the fa -closed neighborhood.

Definition 1.9: A topological space (X, τ) is called fa - Hausdorff, if for each two distinct points x and y in X , there exist disjoint fa -open sets U, V such that $x \in U$, and $y \in V$.

In the following theorem we give some properties of fa -Hausdorff space.

Theorem 1.10 : Let. X be a FaTVS , then X is fa - Hausdorff if and only if for each $x \in X$ there exists U_0 satisfies $x \notin U_0$.

Proof: (a) \rightarrow (b) Let $x \in X$ be a non-zero vector. Then, there are disjoint fa -neighborhoods U of 0, and V of x , where U belong to the collection of neighborhoods of 0, V belong to the collection of neighborhoods of x and $x \notin U$.

(b) \rightarrow (a) let $x, y \in X$ such that $x \neq y, U_0$ is a fa -neighborhood for 0 with $x-y \notin U_0$. By part (a) of Theorem 1.8, there exists fa -neighborhood W of 0 such that $W+W \subseteq U_0$ W is balanced (from part (b) of Theorem 1.6). Now suppose that the sets $V_1 = x+W$ and the set $V_2 = y+W$. Therefore, V_1, V_2 is a fa -neighborhood of x, y , respectively. We need to show that $V_1 \cap V_2 = \emptyset$, assume the point $s \in V_1 \cap V_2$ then

$-(s-x) \in W$, note that W is balanced and $s-y \in W$, and this leads to

$x-y = (s-y) + (-(s-x)) \in W+W \subseteq U_0$ which is a contradiction. So that we have $V_1 \cap V_2 = \emptyset$.

Thus, the space X is fa - Hausdorff.

Corollary 1.11: Let X be a FaTVS , then the following statements are equivalent

(a) Let. X be a fa - Hausdorff.

(b) The intersection of all neighborhoods of 0 is $\{0\}$.

(c) The intersection of all neighborhoods of x is $\{x\}$.

Theorem 1.12: Let X be FaTVS , then X is fa -Hausdorff iff one-point subset of X be fa -closed in X .

Proof: Let $x \in X, y \in X \setminus \{x\}$, and $x \neq y$ that means $x-y \neq 0$, therefore there exists a fa -neighborhood U for zero satisfies $y-x \notin U$. Then there exists fa -closed balanced neighborhood W of 0 with $W \subseteq U$ (by theorem 1.8,b). Which implies that $y-x \notin W$ then

$y - x \in X - W$. Therefore $y \in (X - W) + \{x\}$, also, $(X - W) + \{x\}$ is fa -open, W is fa -closed, $(X - W) + \{x\}$ contained on $(X - \{x\})$. Which shows $X/\{x\}$ is fa -open, thus $\{x\}$ is fa -closed. Conversely, let $x \in X$ and assume the singleton $\{x\}$ is fa -closed. From Theorem 1.7 the set $\{x\} = Cl_{\text{fa}}\{x\} = \bigcap \{U + \{x\} : U \text{ is } \text{fa}\text{-neighborhood for zero}\} = \{W : W \text{ is } \text{fa}\text{-neighborhood of } x\}$ where $W = U + \{x\}$. Thus by Corollary 1.11, X is fa -Hausdorff.

Definition 1.13: A topological space (X, τ) is called fa -compact if for any cover for X by fa -open subsets have a finite subcover.

Theorem 1.14 : Let C, K be subsets in a $\text{FaTVS } X$, and $C \cap K = \emptyset$ such that C is a fa -closed, and K fa -compact. Then there exists a fa -neighborhood U for 0 such that $(K + U) \cap (C + U) = \emptyset$.

Proof: If $K = \emptyset$, then the proof is trivial. Otherwise, let $x \in K$, and $x \neq 0$. Then, $X - C$ is an fa -open set of 0 . Since the addition mapping is fa -irresolute and fa -continuous. Therefore, fa -neighborhood U for zero satisfies $3U = U + U + U \subset X - C$. Define $\tilde{U} = U \cap (-U)$ which is fa -open, symmetric and $3\tilde{U} = \tilde{U} + \tilde{U} + \tilde{U} \subset X - C$. That leads to $\emptyset = \{x + x + x, x \in \tilde{U}\} \cap C = \{x + x, x \in \tilde{U}\} \cap C$ intersected $\{y - x, x \in \tilde{U}, y \in C\}$ and $\tilde{U} \cap \{C + \tilde{U}\} \subset \{2x, x \in \tilde{U}\} \cap \{y - x, x \in \tilde{U}, y \in C\}$. This is for one point. Now we have K is fa -compact, then by the above argument for every $x \in K$, we have a symmetric fa -neighborhood V_x s.t. $(x + 2V_x) \cap (C + V_x) = \emptyset$. The sets $\{V_x : x \in K\}$ are a fa -open that covers K , and since K is fa -compact subset therefore for finite number for points $x_i \in K, i = 1, \dots, n$, we have

$K \subset \bigcup_{i=1}^n (x_i + V_{x_i})$. Define the fa -neighborhood V of 0 by $V = \bigcap_{i=1}^n V_{x_i}$ Therefore $(K + V)$ intersected $(C + V) \subset \bigcup_{i=1}^n (x_i + V_{x_i} + V) \cap (C + V) \subset \bigcup_{i=1}^n (x_i + 2V_{x_i}) \cap (C + V_{x_i}) = \emptyset$, and the proof is finished

Lemma 1.15: Let U be fa -open subset of a $\text{FaTVS } X$, and A be any subset such that $U \cap A = \emptyset$, then $U \cap Cl_{\text{fa}}(A) = \emptyset$.

Proof: Let $x \in (U \cap Cl_{\text{fa}}(A))$. Thus $x \in Cl_{\text{fa}}(A)$, U is fa -neighborhood for x , since U is fa -open subset, then $X - U$ is fa -closed subset contain A , so that $Cl_{\text{fa}}(A) \subseteq X - U$, and $x \notin Cl_{\text{fa}}(A)$ which implies a contradiction, therefore $U \cap Cl_{\text{fa}}(A) = \emptyset$.

Corollary 1.16: Suppose that C , and K are disjoint sets in a $\text{FaTVS } X$ with C fa -closed, K fa -compact. Therefore, there fa -neighborhood U for zero satisfies $Cl_{\text{fa}}(K + U) \cap (C + U) = \emptyset$.

Proof: In theorem 1.14 we have for any disjoint fa -closed C set and fa -compact set K , so that there is a fa -neighborhood U for 0 such that $(K + U) \cap (C + U) = \emptyset$. The set $C + U = \{y + U : y \in C\}$ is a fa -open set, then by lemma 1.15 $Cl_{\text{fa}}(K + U) \cap (C + U) = \emptyset$.

Definition 1.17: Let X be a vector space with field K , an algebra dual for X is the collection of linear functional which is defined in X and represented by X^* .

Theorem 1.18: Let X be a FaTVS and $0 \neq f \in X^*$, then $f(F)$ is fa -open in K whenever F is fa -open in X .

Proof: Let F be a non-empty subset of X , and $0 \neq x_0 \in X$ with $f(x_0) = 1$. Then, for any point $a \in F$, we have to prove that $f(a) \in \text{Int}_{\text{fa}}(f(F))$. F is fa -open neighborhood for a then, by Theorem 1.4 we have $F - a$ is fa -neighborhood of 0 . By Theorem 1.6 $F - a$ is absorbing, then there exists $\epsilon > 0$ such that $\lambda x_0 \in F - a$ for $\lambda \in R$ with $|\lambda| \leq \epsilon$. Thus, for any $\beta \in R$ with $|\beta - f(a)| \leq \epsilon$ we have the $(\beta - f(a))x_0 \in F - a$, thus $f((\beta - f(a))x_0) \in f(F - a)$, $(\beta - f(a))f(x_0) \in f(F - a)$ $(\beta - f(a))(1) \in f(F - a) = f(F) - f(a)$ which lead to $\beta \in f(F)$, $f(a) \in [\beta - \epsilon, \beta + \epsilon]$, $f(a)$ is interior point so that $f(a) \in \text{Int}(f(F)) \subseteq \text{Int}_{\text{fa}}(f(F))$, which shows that $f(F) = \text{Int}_{\text{fa}}(f(F))$.

Note that an extremely point of a convex set in a vector space X is a point which is not an interior point of a segment.

Lemma 1.19: [10] Let X be a vector space, and $0 \neq A \subseteq X$. For $x \in A$ the following statements are equivalent.

- 1) x is extremely point on A
- 2) if $a, b \in A$ such that, $x = \frac{1}{2}(a+b)$, then, x equal to a equal to b .
- 3) let. $a, b \in A$, with $a \neq b$, let $\lambda \in (0, 1)$, $x = \lambda a + (1-\lambda)b$. Then we have either $\lambda = 0$, or $\lambda = 1$

Theorem 1.20: Let X be $F\alpha$ TVS, and $F \subseteq X$ be convex. Therefore, $[f\alpha\text{-interior}(F) \cap (\delta F)] = \emptyset$

Proof: If $Int_{f\alpha}(F) = \emptyset$, the proof is trivial. Suppose that the $Int_{f\alpha}(F) \neq \emptyset$ and let $x \in Int_{f\alpha}(F)$. Therefore, there is a $f\alpha$ -neighborhood U for 0 s.t, $x+U \subseteq F$. Define the mapping $\varphi: \mathbb{R} \rightarrow X$ where $\varphi(\mu) = \mu x$ continuous at $\mu = 1$, for this the $f\alpha$ -neighborhood $x+U$, there is an $s > 0$ s.t, $\mu x \in x+U$ whenever $|\mu-1| \leq s$. In particular, we have $(1+s)x \in x+U \subseteq F$ and $(1-s)x \in x+U \subseteq F$. Now consider $x = \lambda(1+s)x + (1-\lambda)(1-s)x$ and take $\lambda = \frac{1}{2}$. So that $x = \frac{1}{2}(1+s)x + (1-\frac{1}{2})(1-s)x$, which leads to the point x which is not extremely on F .

Conclusion: Throughout this research we have been proved some results, namely the fuzzy- α topological vector spaces satisfies, the property of any neighbourhood for 0 containing a neighborhood for 0 which is balanced, $F\alpha$ TVS satisfies the separation axiom (fuzzy- α hausdorff) and in a fuzzy- α topological vector space the fuzzy- α -interior of a convex set didn't intersect with the boundary of the set.
